(7) *The restriction and regulation of interstate and international emigration of persons suffering from the disease.*—History teaches that one of the most potent factors in the spread of tuberculosis has been the migrations of consumptives. The will-o'-the-wisp of a climate which would cure consumption has been indirectly the means of infecting the world. There is scarcely a country which has not at one time been free from the disease and for that reason become a resort for those suffering from it. In turn the place became a place of exodus and a source of infection to some newer country. All of America was virgin soil for the disease when Europeans came here. New York, Pennsylvania, in fact every State and Territory, has in turn been a resort for the consumptive and was at one time believed to possess a curative climate. Unfortunately this seductive method of spreading the disease is still in active operation, and with our modern facilities for travel has become more prolific than ever. It probably furnishes the most frequent source of infection to the wealthier class, those who can change their place of abode with every change of season. It infects our hotels, our sleeping cars, and our staterooms. It has made tuberculosis as rampant under the sunny sky of California as in the changeable climate of the Atlantic Slope. What is the remedy? International emigration of persons suffering from tuberculosis should be entirely stopped. This is a matter for the Federal Government, and in the United States is, I believe, through the efforts of Surg. Gen. Wyman, already receiving attention. Foreign travel of persons in the early stage of the disease before there is any breaking down need not be interfered with. Interstate emigration should be restricted and regulated. This would of course be a matter for the States and in certain cases for cities to take charge of. Persons in the infectious stage of the disease should be discouraged as much as possible from changing their places of residence, and when they do make changes it should be with the consent and under the supervision of the health officer. Some of the Territories and newer States which are as yet comparatively free from tuberculosis would probably find it to their advantage to shut out from their borders all consumptives in the infectious stage who seek admission for climatic reasons. Such an embargo would of course not need to be applied to those in whom the disease has not yet reached the breaking-down stage, and to those that have, it would be more of a benefit than an injury as they can no longer be saved by a change of climate and are frequently seriously injured by it.

(8) *The retirement of all consumptives in the infectious stage from occupations in which they can infect others, and the pensioning of those who are dependent on their own labor for a living and who can not be maintained in hospitals.*—Because of the prolonged duration of tuberculosis it is necessary for the poor to follow their callings in life during the infectious period of the disease. We consequently have consumptives for cooks, waiters, barbers, fruiterers, grocers, butchers, dairy-

men, nurses; in short, we have them in every walk of life. To ask these people to give up their positions is a great hardship unless some provision is made for their support and that of the destitute families depending upon them. As the giving up of their positions would be in the interest of the public good, they ought to be retired at public expense. Every case of tuberculosis which has arrived at the infectious stage ought to be retired from any position where it could infect others, and either be given admission into a hospital or paid a pension sufficient for maintenance. For the destitute family depending upon the labor of the person affected there would be ample provision in the eleemosynary institutions already in existence. Retiring and pensioning persons suffering from a disease which is a menace to others will no doubt be considered too advanced ground in preventive medicine to be considered seriously at present. It will, however, force itself upon our attention in the near future. The justness of the principle involved has already been admitted in the compensation allowed for diseased cattle slaughtered by direction of the Government. By the establishment of special hospitals for the treatment of persons suffering from consumption, the consumptive poor of the country could be maintained at a quite reasonable expense. The taxation which would have to be imposed upon the individual to enable the Government to carry out such a plan would be returned an hundredfold in the protection afforded against the disease. Tuberculosis carries off at least 100,000 people annually in the United States. It has been estimated that this entails a loss in public wealth of about \$500,000,000 a year. A small fraction of this great loss well expended would go a long way toward wiping out the disease.

---

#### THE CLIMATE OF WESTERN NORTH CAROLINA, WITH A CONSIDERATION OF THE RELATIVE VALUES OF HIGH AND MEDIUM ALTITUDES IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

By KARL VON RUCK, M. D., of Asheville, N. C.

In speaking of North Carolina, and especially its mountainous part in the western portion of the State, which is already widely and favorably known on account of its climate, I shall necessarily have to repeat what I have stated elsewhere at various times and occasions, and what has been stated by others before my time. That part of western North Carolina known as the Asheville plateau has, in the parlance of climatologists, only a medium elevation of some 2,500 feet above sea level. There are, however, within a radius of 30 miles of Asheville and encircling the plateau, both higher and lower levels, and within a few hours' journey we can reach elevations varying from 1,200 to nearly 7,000 feet. If it should appear desirable these elevations can be made use of in the climatic treatment of phthisis and other diseases. Some writers, and especially such as practice at much greater elevations than that of the Asheville plateau, convey to us the impression that only the higher levels are really curative in the climatic treatment of phthisis, and that such levels as the one to which I am now calling your attention are a sort of medium, "neither good nor bad." They therefore almost deny to the medium and lower level resorts the right of existence, as being of use only as a makeshift at best, whereby the chances for the patients' ultimate recovery are liable to be trifled away. If this view is really warranted by the facts, a prompt recognition of it by all who have occasion to send away phthisical patients for climatic treatment would be most desirable. The inconsistency of the position is, however, manifest, apart from the fact that clinical experience disproves the assertion. If elevation is beneficial at all, and no one experienced in phthiso-therapy denies that, the most

that could be claimed theoretically would be that it is relatively so, according to the degree obtained, for it would be strange indeed that 2,500 feet should count for nothing, whereas 6,930 feet are auspicious. I hope, however, to show you that a golden mean is not to be ignored any more in this than in many other of our endeavors, and that, other things being equal, a medium elevation presents advantages over high levels like Colorado and other portions of the Rocky Mountain system by which we find ourselves clearly the gainers. At a medium elevation of from 2,000 to 3,000 feet, like the one of the Asheville plateau, the heart action is not disturbed to such a degree as is the case at elevations much higher and, while the influence of the change is perceptible at lower levels also, patients do not suffer on account of shortness of breath and palpitation of the heart so frequently complained of by consumptives in going to high altitudes. The shortness of breath is in part induced by the rarefied atmosphere, of which a proportionally larger volume is required to convey to the blood an adequate amount of oxygen. In health this is to a degree compensated by deeper respiration, but the patient who has his respiratory capacity perceptibly decreased on account of the changes which have occurred in the lung can make up the deficiency for the most part only by increased frequency, or not at all if the elevation has reached a considerable degree. To this comes the additional disadvantage that the degree of possible lung expansion is less in proportion as we decrease the atmospheric pressure, which was demonstrated as long ago as 1850 by Pravaz, and subsequently by Lange and others; and I have recently repeated their experiments, both under increased and decreased atmospheric pressure in the pneumatic cabinet. I find, as they did, that if under ordinary air pressure a healthy person performs complete expiration and thereupon attempts forcible inspiration through a tube connected with a mercury manometer the mercury is raised  $4\frac{1}{2}$  to 5 cubic centimeters. If now the air chamber is closed and the pressure in it increased, upon a repetition of the experiment the mercury rises higher in proportion to the increased pressure. If the pressure in the chamber is diminished the result is reversed and lesser values are obtained than under ordinary pressure, corresponding again to the degree of rarefaction. By practice higher values are obtained in either case, but the relation of the rise of the mercury in the manometer to pressure and rarefaction remains constant. The same experiments carried out with patients suffering from pulmonary tuberculosis showed identical results, but it was noted that the inspiratory and expiratory forces were always below the normal, and even in cases in comparatively early stages a diminution of 15 to 25 per cent was the rule. It is therefore erroneous to believe that the respiratory capacity of the lungs is greater under diminished air pressure. On the contrary, it is proportionally less, as is also the degree of oxygenation of the blood, which is dependent upon it and upon the density of the atmosphere. If, in addition, we observe the effects of greatly diminished air pressure upon the circulation of the phthisical patients, and especially of such as have advanced beyond the very early stages, we find that it is not borne as well as it is in the cases of persons having no lung disease, while in all cases the peripheral circulation is increased as the surface pressure is diminished. In health the veins can empty themselves freely into the right auricle and ventricle, whence under increased frequency of respiration, with unobstructed lung tissue, the flow through the pulmonic system to the left heart is equally free, and in this manner an equilibrium between the greater and lesser circulation is maintained. If, however, the lung can not fully expand from the too great rarefaction of the air, and if the lung suffers in addition in its expansion by the presence of pleuritic adhesions, thickening, or exudates, or if the parenchyma of the lung is itself the seat of inflammatory changes, infiltrations, or consolidations, then there is a mechanical obstruction placed in the lung to the free flow of blood from the right ventricle through the lung to the left auricle, and the equilibrium between the

lesser pulmonic and the greater systemic circulation is easily disturbed or lost. The heart is now called upon to compensate the disturbance by increased power and frequency of contraction, and under rest, or with a strong heart muscle, when the obstruction is not too formidable, this equilibrium may be obtained or reëstablished. If the conditions for perfect equalization of the circulation are not present, then passive pulmonary congestion and heart strain are the inevitable results. In some cases, at great elevations, this can be only avoided by absolute rest in the recumbent position, while with others it is impossible under all circumstances, and the patient, unless quickly removed to a lower level, soon dies, either from pulmonary hæmorrhage, edema, or heart failure. In still others the congestion leads to renewed or increased active, possibly destructive, changes and their consequences, and in all this equalization of circulation is more readily disturbed by comparatively slight causes, which at lower levels are inoperative. The greater the elevation the greater is the liability for these undesirable effects. At high altitudes much less exercise is therefore possible without resulting in pulmonary congestion and heart fatigue—conditions which cause shipwreck in the journey for health of the consumptive more frequently than all other preventable causes combined.

Consumptives are more liable than others to pulmonary congestion and heart fatigue at any level, first, because of the obstruction to the circulation produced by the lung disease, and second, because of the accompanying nutritive disturbances and anæmia. The heart in most cases is already damaged, weak, and irritable and seldom in a condition which justifies us to make great or unusual demands upon it, and this is often true even in the early stages of the disease. It follows, therefore, that we can not employ altitude in the treatment of phthisis on the principle that "the greater the elevation, the better for the patient," and I find from practical experience that even at a medium elevation of 2,350 feet the tendency to heart fatigue is more manifest than I have found it to be at places with lower elevations. I have thus had occasion to advise the removal of patients to lower levels because of circulatory disturbances, in the absence of actual heart disease, which were unquestionably due to the reduced atmospheric pressure, inasmuch as they did not exist before leaving home, and promptly subsided when my advice was complied with. Any unusual demand upon the heart, be that on account of change in the atmospheric pressure, physical exercise and labor, or other strain, must therefore have our careful consideration and be avoided unless in cases where we are reasonably sure that the heart is adequate to the demand and that our patient will be benefited thereby. The liability of consumptives to heart strain with its consequences exists also when going from high altitudes to considerably lower levels and, other things being equal, the effects are in proportion to the degree of change in the atmospheric pressure and the rapidity with which the change is made. At a medium elevation these effects are better borne, because the strain is less and patients still in a condition where improvement and cure can reasonably be looked for can come to and return from lower levels with greater safety.

The danger to patients of returning to seacoast localities who were considered cured at the high elevations of Colorado and New Mexico is recognized even by the laity and physicians both at the elevated stations and at home recognize the fact by advising against it, so that it practically means exile from home and friends and from former associations for life to send consumptives to very high elevations, to say nothing of the dangers and disadvantages to which they would be thereby exposed. If it were true that by these means only a relative cure can be accomplished, the sacrifice and risk would be imperative, although regrettable. There are still other disadvantages of high-level resorts, among which I may mention the great ranges of temperature. Extremes, not only in altitude but also in

temperature, are undesirable for the consumptive. If he is to live out of doors as much as possible he must avoid great degrees of cold, against which he finds it difficult to protect himself, especially when not taking active exercise, and against the enervating extremes of heat he can not protect himself at all. With these extremes occur great and sudden variations in temperature, and these the consumptive feels to his detriment in any stage of the disease.

According to Dr. J. W. Gleitsmann, who made temperature comparisons between some high altitude resorts of Colorado and the medium elevation of Asheville, N. C., in 1874, a temperature of 90° F., with a maximum of 102° F., occurred in Denver, Colo., fifty times, and at Colorado Springs thirty-nine times during the same summer, when in Asheville, N. C., only once a temperature as high as 88° F. was observed. He also found similar, only reversed, extremes for the winter months, during which, owing to its geographical position and lower altitude, the Asheville plateau, with an average of 46° F. for the winter months, is free from severe cold weather; snow rarely falls, and when it does the sun usually melts it away on the same day. That a happy medium is best is also true as to a "comparatively dry climate," which constitutes another desirable factor in the climatic treatment of phthisis. Too great dryness of the air is, however, undesirable, becoming frequently a source of irritation to the lungs and throat, and Dr. Rudi, of Denver, recognizing the disadvantage, advises the generation of steam in the patient's sleeping apartment.

Great dryness of the air is associated with prolonged dry spells and the absence of rain, which means a large amount of dust floating in the air, the inhalation of which should be avoided in all lung and throat affections. At lower levels the air contains relatively more moisture, and upon the Asheville plateau the average humidity for the entire year is 65 per cent, while at some points in Colorado and New Mexico it is no doubt much lower. Sixty-five per cent is, however, relatively dry, and compares favorably with the lowlands, where the average is in the neighborhood of 80 per cent. The number of clear and fair days at a given climatic resort is also important, as upon them depends largely the patients' ability to derive the full benefit of climatic treatment in living out of doors as much as possible. Many of the localities with medium or lower elevations can compare in this respect with the higher levels, and the Asheville plateau has averaged twenty-five clear and fair days for each month in the five years since the establishment of the U. S. Weather Bureau in 1888. In the past year there have not been more than three or four days on which my patients did not have the advantage of out-of-door life on account of unfavorable weather. The Asheville plateau can therefore claim freedom from all extremes in elevation, temperature, or humidity; it has every condition favorable to out-of-door life; it is an all-year favorable locality where in the residence of the invalid no change is required with change of season.<sup>1</sup> It is easily accessible, being within twelve to twenty-four hours' travel of the Eastern, Middle, and Southern States, obviating the more serious and frequently detrimental fatigue from days of travel to localities of greater elevation and greater distance. That such resorts of medium elevation deserve consideration is apparent from the estimation in which they are held by the profession, and much lower levels than the Asheville plateau have shown excellent records in improvements and recoveries obtained, and the facts presented regarding the disadvantages of high altitudes outweigh in my judgment any supposed advantage claimed for them; but apart from the foregoing considerations we must consider as our best guide the clinical results obtained and compare them.

Speaking for western North Carolina, and the Asheville plateau in particular, I am able to record equally as good results, if not better, as have ever been shown

<sup>1</sup>For more particulars reference is made to the meteorological table from the records of the U. S. Weather Bureau for the years 1888 to 1892, attached at the end of this paper.

for the high-level resorts, and, without going into details, I can say that in the truly early stage I have for several years past obtained 100 per cent of recoveries in all cases who remained a sufficient length of time to justify the expectation, while not a single early-stage case has failed to show improvement from even a comparatively short season of residence. The high-level resorts can not possibly do better, and with these results the plea for more than medium elevation must fall to the ground. I have now records of 518 cases treated and discharged more than two years and as long as five years ago. The permanency of the results in these cases was inquired into this past winter by correspondence with patients, their relatives, or their physicians. With but few exceptions, they have all returned to their previous places of residence and the answers received show that a cure or permanent arrestment of the disease continues in 181, or 35 per cent; 296 others, or 56 per cent, continue still improved as compared with the time of their arrival at Asheville; and only 70 patients have grown worse or have died. Not until better results and of equal duration can be shown for the high-altitude resorts need the profession seriously consider any possible advantage they may claim over lower or medium levels.

In conclusion, I desire to say that I am not unmindful of excellent results obtained in high altitudes, especially in the early stage, nor of the fact that the statistics of the high-level resorts are seriously clouded by the unfavorable course and bad results in cases at all advanced in the disease and who were erroneously sent to them. I claim, however, that such early-stage cases could have derived the same benefits at lower levels without subjecting them to the dangers pointed out in the earlier part of this paper, and that many of the advanced cases who fail to improve or grow worse at high altitudes could derive benefit at places having only a medium elevation.

*Summary of meteorological records for the years from 1888 to 1892, inclusive.*

[The United States Weather Bureau meteorological observatory at the Winyah Sanitarium, Asheville, N. C. Elevation, 2,350 feet; Lat., 35° 36' N.; Long., 82° 26' W. Hours of observation, 7 a. m., 2 p. m., and 9 p. m.]

## OBSERVATIONS ON THE CONVENIENCE OF ESTABLISHING A UNIFORM AMERICAN INTERNATIONAL SYSTEM OF QUARANTINE AND MARITIME HYGIENE.

By JUAN J. ULLOA, G. of San José, Costa Rica, Central America.

My first intention was to deliver my short essay in Spanish, because, it being my own language, I can express myself better in it than in yours. But as the English-speaking doctors constitute the great majority I will try to make myself understood in English. Without any pretension on my part of saying anything new, I simply wish to excite my illustrious companions to the discussion of a topic which in my humble opinion is of the utmost importance to all the nations which compose the occidental hemisphere.

I do not consider it worth while to refer to the interest with which the entire civilized world treats all questions appertaining to hygiene in its manifold applications, convinced as they are of the importance of the branch whose principal object is to look for the causes of disease and to endeavor to find the best manner of destroying them, or at least of diminishing their deleterious influence on the health and well-being of the human race. In all nations which march forward with the century and which keep abreast of modern science hygiene receives the greatest attention, and in consequence its teachings are accepted and laws and regulations are enacted to enforce its precepts. This conforms naturally to the conviction which those who rule the destinies of civilized nations entertain regarding the incalculable benefits to be derived from effective compliance with the scientific action of the medical branch whose principal object is to prevent disease. Only in those unfortunate countries whose rulers try to darken the powerful light of Edison's century and who sacrifice all interests to their selfishness and to the convenience of their own friends or parties, hygiene, like many other grand achievements, has no opportunities and almost no attention is paid to it. Taking this into consideration, we naturally come to the conclusion that in the great majority of those backward countries the inhabitants suffer not only from endemic and epidemic

diseases which should not produce so much harm nowadays, but from others which, according to the achievements of modern science, should be stamped out almost completely. This state of affairs is not only harmful to the interests of the country in which so little attention is paid to hygienic precepts, but imperils all the other countries with which it has commercial relations, and which at any moment may receive the contagion. At present, when medical science has progressed so much, and when clinical observation, together with the microscope and chemical analyses, has made so many conquests, carrying light into the darkness, which involved all the avenues which lead to the knowledge of the productive causes of the ailments of mankind, it is necessary that we as apostles of health should help to the utmost of our capability the establishment in our respective countries of a hygienic service which shall correspond to modern requirements. It seems to me that this subject suggests, on our part, a very important duty to our several countries, and that we must work diligently until we succeed in bringing our peoples as near as possible to the position occupied by those nations which are the standard bearers of progress, and which, convinced of the importance of hygiene give to it a prominent place in their public administration. Unfortunately, in the great majority of our Spanish-American countries hygiene does not receive the attention it deserves, and we generally have only imperfect hygienic services in charge of incompetent persons, who very often ignore even the most rudimentary principles of the branch to which they are dedicated. If we refer to our seaports we find that, generally speaking, they lack the indispensable sanitary service, endangering not only their local interests, but those of the countries with which they are in contact. The official physicians are badly compensated, and in consequence we rarely have able men in charge of the important positions of health officers. In the great majority of the ports of Spanish-America they do not have quarantine structures properly situated and with the necessary requirements. In one word, we do not have the organization nor the complete hospital conveniences to isolate cases of contagious diseases as they may appear, and besides we are not prepared to properly enforce quarantine among the passengers and vessels which may come from infected ports. To this deficiency in what appertains to prophylactic medicine in our ports are due the extraordinary measures taken by our Governments in cases of probable danger, as, for example, from the importation of Asiatic cholera. In these cases our Governments dictate extreme measures which should not be tolerated nowadays, when the character of contagious diseases, their periods of incubation, and their methods of propagation are known. Last year on account of the menace of cholera in Central America, Colombia, Brazil, and other countries of South America, the ports were entirely closed to all vessels arriving from infected or suspected ports. Now, this measure, it matters not in what light we may consider it, is extremely inhuman, and this consideration is in itself sufficient to admonish us to prepare ourselves so that we may receive those vessels without any danger, attend those who may be unavoidably ill, and do in due form all that may be required for the disinfection of baggage, merchandise, etc. Not only the dictates of humanity, but the commercial interests of our countries, demand the establishment of a good system of quarantine which will interfere as little as possible with traffic, so as to injure our commercial prosperity to the smallest extent. All these considerations have induced me to propose to the high judgment of this distinguished assemblage a project for the establishment of an international system of quarantine and maritime hygiene obligatory upon all the different sections which form the world of Columbus. As this subject would have to be a matter of necessary legislation in our respective countries, I think that we might confine ourselves for the present to discussing its importance, and if my illustrious compeers should be of my opinion a commission might be appointed by the Pan-American Medical Congress to study the matter

properly, and to propose whenever and wherever the congress may designate the best plan to carry out the project. Recapitulating, I would say: I propose the establishment of a system which might be called "the Pan-American system of quarantine and maritime hygiene." The foundation of the whole system should rest on a general code, which should comprise all that is accepted to-day by science in this matter. This code should be adopted by all the nations of the American continent and adjacent islands. Each constituent country should have a national board of health residing in its capital, and also auxiliary boards in other cities, and principally in the seaports, all subordinate to the national board of health. Each national board of health should be the central medical authority for each country, and all the national boards should be under the general direction of a central international board of health, which should be the head of the whole system. The central board should be established in an important city well situated for communication with all the countries which constitute the system. I propose as the desired point for the central board of health the city of Washington, D. C., not only because it is the capital of our eldest and most advanced sister, but on account of its especial position, which best adapts it to serve as a center to the entire system. The details of organization of the several boards, officers, etc., and the by-laws, general and special, it seems to me, should not be entered into here, because they must be taken into consideration by the commission, to whose appointment I referred before. To carry to a happy solution the project which I have the honor to initiate, I believe it would be advisable that, having accepted the idea, the Pan-American Medical Congress should ask the Government of the United States to propose to the governments of the countries which form the continent and adjacent islands to appoint delegates with full powers to discuss and act upon the subject in question at the meeting which should take place as soon as possible in accordance with the resolutions adopted by the Pan-American Medical Congress. Once established, the Pan-American system of uniform quarantine and maritime hygiene might enter into an understanding with the systems prevailing in the Old World, and we might ultimately come to an agreement in the matter that would lead to the adoption of universal quarantine regulations. The importance of the system which I propose can hardly escape the approval of my able fellow-members whose attention I hope to interest. The establishment of a hygienic organization of this class will not only serve to protect the health of our respective countrymen, but it will be of immense service to the commercial transactions which signify so much to the material prosperity of all, but more especially to that of our new countries. Moreover, the strict observance of fixed precepts, scientifically based, obligatory on all our countries, will be of service also to prevent those countries which might be unfortunately visited by an epidemic from communicating it to all the others with which it is connected by travel and transportation. As a matter of course, once the system is well established, all the appointments of medical officers will be properly made by the national boards of health, which will also see to it that all the quarantine requirements shall be such as to give complete satisfaction. A quarantine system well established will make it, if not impossible, at least very improbable for the United States and Europe to send Asiatic cholera to our Spanish-American countries, and at the same time will protect them from receiving yellow fever from us.

I will conclude, hoping that my incoördinate ideas will serve as a starting point to a thorough study of the subject in question, which will have as a happy consequence the establishment of the system which I have had the honor of proposing to your consideration. If we should succeed in carrying it through, I am fully convinced that it would become a great blessing to our countries especially and a benefit to the world at large; and unless such measures be adopted we can never aspire to be looked upon as progressive in medicine or in commerce.

## HISTORIQUE DU SIPHON. GAZÉIFICATION PAR L'ACIDE CARBONIQUE LIQUIDE.

Par le Dr. PROSPER DE PIETRA SANTA, de Paris.

## I.

Parmi les questions d'actualité les plus étudiées et les mieux élucidées par la Société française d'hygiène, au triple point de vue technique, industriel et sanitaire, je n'hésite pas à placer celle de l'eau de Seltz à Paris. Effectivement, elle a été l'objet : (1) De communications importantes faites en séance par MM. Mondollot, Durand-Fardel, Gantrelet et Peyrand, communications qui ont donné lieu à d'intéressantes discussions. (2) D'analyses chimiques et bactériologiques entreprises dans le laboratoire d'analyses de la Société par MM. Lebaigne, Dupré et en dernier lieu par MM. Ferdinand-Jean et Bruhat. (3) D'expériences et de constatations variées instituées par l'une de vos commissions sous la présidence de M. Fichet, alors que s'est posé le problème de la gazéification possible des eaux par l'acide carbonique liquide. Dans ces diverses circonstances, la Société restait bien dans son programme d'applications pratiques puisqu'il s'agissait d'établir les meilleures conditions de fabrication d'une boisson hygiénique par excellence, et pouvant en outre être fournie aux consommateurs à des prix des plus abordables pour les petites bourses.

D'autres sentiments non moins respectables avaient stimulé le zèle de plusieurs de nos chers collègues, en portant la lumière et la vérité dans une question d'hygiène industrielle intentionnellement obscurcie : d'une part, par la concurrence déloyale des propriétaires de l'eau anglo-allemande d'Apollinaris ; de l'autre par les craintes, les appréhensions, voire même les accusations formelles de savants chimistes qui semblent s'être fait une spécialité de la plombophobie.

Si, en ma qualité d'inspecteur des établissements d'eaux minérales du département de la Seine, j'ai dû prendre une part assez active dans cette levée de boucliers contre des procédés peu corrects et inconsidérés, c'est que j'avais à cœur de défendre une corporation honnête, dans laquelle nous comptons plusieurs collègues dévoués. A aucun moment, du reste, je n'ai hésité à me départir des instructions souvent prime-sautières de l'administration préfectorale, que je me suis toujours efforcé de représenter dans ses attributs de surveillance, de contrôle et de protection. J'avais devant moi un syndicat des fabricants d'eaux gazeuses, dans lequel figuraient des industriels, les premiers intéressés à l'amélioration et au perfectionnement de leurs produits. En faisant pour ainsi dire cause commune avec eux, j'arrivais au seul but désirable, celui du respect le plus absolu des préceptes de l'hygiène, des exigences légitimes de la santé publique.

Lorsque je suis entré dans l'inspection, en 1874, j'ai trouvé l'industrie des eaux gazeuses en face d'objections, de réserves, d'accusations même, d'une certaine gravité. Au moment de la quitter, en 1893, par suite du rattachement du service au laboratoire municipal d'analyses, je puis affirmer ici hautement, comme je l'ai fait naguère devant l'Académie des sciences, qu'à Paris, à l'heure présente :

L'eau de Seltz, boisson hygiénique de premier ordre, peut être désormais livrée à toutes les classes de la population dans des conditions irréprochables de pureté, d'agrément et de salubrité.

J'ai donc le droit de féliciter la Société française d'hygiène de son intelligente initiative et du succès de cette campagne sanitaire, en remerciant vivement ceux de ses membres qui se sont constitués de zélés collaborateurs.

MM. Marié-Davy, Mondollot, Pellet, Lebaigne, Dupré, Gantrelet, Peyrand, Ferdinand-Jean, Bruhat, Fichet et Cerckel.

## II.

Je me propose maintenant d'exposer brièvement, non pas toutes les phases de la question, mais bien les deux principales relatives aux progrès réalisés : (1) Dans la construction du siphon. (2) Dans le mode actuel de gazéification. Pour mettre les uns et les autres en pleine lumière, et dans une pensée d'impartialité, je commencerai par rappeler les opinions soutenues dans des publications récentes par deux membres autorisés à l'Académie de médecine, un chimiste, M. Armand Gautier, et un médecin thérapeute, M. Constantin Paul.

Dans le chapitre, Eaux potables, de l'Encyclopédie d'hygiène et de médecine publique (Dr. J. Rochard, tome II, 3<sup>e</sup> fasc., p. 404, Paris, 1890), M. A. Gautier s'exprime en ces termes :

Les eaux gazeuses artificielles, dites à tort eaux de Seltz, s'obtiennent en chargeant l'eau potable, enfermée dans des appareils métalliques généralement en cuivre étamé, d'acide carbonique comprimé dans ces récipients sous une pression de 2 à 4 atmosphères.<sup>1</sup> Ces eaux artificielles ont plusieurs inconvénients : Le principal pourrait être évité si les fabricants pouvaient s'astreindre à n'employer que de bonnes eaux potables ou filtrées à travers des vases de porcelaine ou même de grès. Mais il suffit d'examiner ces appareils, dits siphons, après les avoir gardé quelques jours à la cave, pour y constater, le plus souvent, des parcelles ou flocons de matière organique en suspension ou accumulée au fond du récipient. De telles boissons présentent les inconvénients des eaux potables non filtrées, boissons peu agréables qui deviennent dangereuses en temps d'épidémie.<sup>2</sup>

Un second désavantage de ces eaux dites de seltz, c'est qu'elles contiennent souvent, comme je l'ai démontré ailleurs,<sup>3</sup> et comme je m'en suis assuré de nouveau depuis en maintes occasions, du plomb dissous ou en suspension à l'état d'hydrocarbonate.

Ce dangereux métal est emprunté aux appareils métalliques en cuivre étamé souvent à l'étain plombiféré, où l'on a chargé ces eaux d'acide carbonique sous pression, condition qui favorise l'attaque du métal.

Cette dissolution du plomb d'étamage est activée à la fois par les matières organiques de l'eau et par le gaz carbonique dissous. Dans tous les cas, il est nécessaire de se préoccuper du danger que fait courir l'usage de boissons si répandues, car chacun connaît les coliques, les céphalalgies, et les autres désordres nerveux qui sont la conséquence de l'absorption continue de ce métal vénéneux même à faibles doses.<sup>4</sup>

Ces eaux ont enfin un dernier inconvénient. Le gaz carbonique n'y est tenu que mécaniquement en dissolution, contrairement à ce qui a lieu dans les eaux gazeuses naturelles, où ce gaz est pour ainsi dire attiré par les carbonates calcaires, magnésien ou alcalin, qui entrent dans leur composition. Aussi le gaz carbonique fortement comprimé des eaux gazeuses artificielles se dégage-t-il violemment dès qu'il arrive dans l'estomac à une température un peu élevée, et par sa masse et sa tension fatigue ou excite outre mesure cet organe.

Comme on le voit par cette longue citation, l'émiment professeur de chimie de la Faculté de médecine de Paris, n'est pas partisan de l'eau de Seltz, et cependant il renonce cette fois à incriminer la teneur en plomb des armatures, ou têtes de siphon dont l'alliage métallique contenait autrefois une préparation de 20 et 25 pour cent de plomb (le degré de tolérance administrative n'étant que de 10 pour cent), mais qui aujourd'hui ne renferme plus qu'une quantité minime de 4 ou 5

<sup>1</sup> C'est là une lourde erreur, car à cette pression la vidange complète du siphon deviendrait impossible. Dans toutes les fabriques, au moment de l'emplissage le manomètre placé sur le ballon gazéificateur marque 10, 12 et 14 atmosphères.

<sup>2</sup> Actuellement toutes les fabriques de Paris sont abonnées aux eaux de source (Dhuys, Vanne), et pourvues de filtres bien conditionnés (filtres Bourgeoise, filtres Maillé, filtres Pasteur-Chamberland, filtres Maignen, etc.).

<sup>3</sup> Le cuivre et le plomb dans l'alimentation et l'industrie. Vol. in 8°, Paris, 1881.

<sup>4</sup> Dans une note insérée aux comptes rendus hebdomadaires de l'Académie des sciences (novembre 1892), de Gautier écrit : " J'ai montré qu'à la dose de 0 gr. 014 de plomb, par jour, pris sous diverses formes, en particulier par les eaux potables, 34 personnes sur 100 seulement ont présenté des phénomènes notoires d'intoxication saturnine. À une dose plus faible, le pour cent tombe nécessairement au-dessous. À la dose de 0 gr. 0005 à 0.0002, par jour, il semble n'y avoir plus d'intoxication possible.

pour cent de plomb. D'une manière générale, on peut dire que les grands fabricants d'appareils (Mondollot, Guéret, Durafort, etc.) ne livrent plus aux fabricants d'eaux gazeuses que des siphons en étain pur et régule avec absence totale de plomb.

Quant à M. Constantin Paul, dans un volume, *Les eaux de table*, publié ces jours derniers en collaboration de M. le Dr. Rodet de Vittel, il ne semble pas connaître l'outillage et le fonctionnement de l'usine.

Après avoir rappelé les expériences faites à Munich par M. le Dr. Leone dans le laboratoire de M. Pettenkoffer, il ajoute :

Cela prouve que l'acide carbonique est un mauvais milieu de culture, et qu'il n'y aurait pas d'inconvénient de boire de l'eau de Seltz si elle ne contenait pas trop souvent un poison qui tue bien plus sûrement que des centaines de mille de bactéries, je veux parler de d'hydrocarbonate de plomb qui s'y trouve dissous, ou en suspension, ainsi que l'a montré A. Gauthier.

Ce plomb provient de l'étamage des têtes de siphon [*sic*]<sup>1</sup> et est dissous avec d'autant plus d'énergie, que l'eau contient des matériaux organiques, et que l'acide carbonique y est dissous sous pression.

Ces eaux ont encore un inconvénient, c'est que l'acide carbonique s'y trouve en dissolution mécaniquement et sous une forte pression ; aussi lorsqu'il arrive dans l'estomac s'y dégage-t-il violemment en distendant l'organe ce qui le fatigue et l'excite inutilement.

En outre, l'eau de seltz artificielle étant généralement fabriquée avec le bicarbonate de chaux et l'acide sulfurique contient souvent une certaine proportion de ce dernier entraînée mécaniquement dans le dégagement gazeux plus ou moins tumultueux de la réaction.<sup>2</sup>

Cette proportion atteint rarement 500 milligrammes par litre : généralement elle est inférieure à 250 milligrammes. La présence de cet acide n'en est pas moins fâcheuse, car elle peut amener des troubles gastriques chez des sujets délicats.

Voilà donc bien établi le bilan des accusations portées contre les eaux de Seltz par deux savants académiciens qui les ont formulées dans le silence de leur cabinet de travail, sans même s'être donné la peine de visiter une fabrique actuelle d'eaux gazeuses, à l'effet de contrôler les faits nouveaux qui réduisent à néant de vieilles assertions passées pour ainsi dire à l'état de légende.

### III.

Sans m'attarder à des démonstrations inopportunes pour ceux qui aiment à conserver leur antipathie pour les eaux minérales artificielles, et toute leur sympathie pour les propriétaires des eaux minérales naturelles, j'entre au cœur même du sujet en exposant le bilan des progrès obtenus.

Ces progrès comprennent : d'une part la construction de siphons perfectionnés, faisant disparaître d'une manière absolue la cause pathogène, le plomb ; de l'autre, la gazéification des eaux de Seltz par l'acide carbonique liquide, chimiquement pur, qui a pour effet immédiat de rendre le liquide antiseptique, antiparasitaire, et d'annihiler l'action des matières premières suspectes (bicarbonates de commerce, blancs de Meudon, acides muriatique ou sulfurique).

L'historique du siphon pendant cette deuxième moitié du siècle montre une série successive d'améliorations et de perfectionnements. A l'origine de la fabrication des eaux de seltz, on se servait de bouteilles en verre, plus ou moins résistantes, mais sujettes à ruptures et à explosions.

En 1837 l'invention du siphon par Savarèsse a doté l'industrie d'un récipient aussi pratique que commode.

<sup>1</sup> C'est assurément de l'alliage métallique de la tête de siphon, et plus spécialement du bec en métal où se fait la vidange qu'à voulu parler l'auteur. C'est en somme l'une des anciennes objections de M. Gautier à laquelle il a dû renoncer par suites d'analyses chimiques des plus précises entreprises par ses contradicteurs.

<sup>2</sup> L'appareil imaginé depuis plusieurs années par Mondollot, dit distributeur automatique de l'acide sulfurique, assure tout à la fois le mélange complet de l'acide et du carbonate terreux et une production régulière d'acide carbonique.

Le siphon se compose, comme chacun sait, de trois parties essentielles: (1) La carafe, jadis de forme ovoïde, maintenant cylindrique, en verre blanc ou colorié, portant gravés sur ses parois le nom et l'adresse du fabricant. (2) La tige, ou tube central, qui traverse la carafe de haut en bas, et par où s'effectue la vidange du liquide carboniqué. Cette tige était à l'origine tout en métal (alliage de plomb et d'étain). Plus tard, au grand profit de l'hygiène, elle a été remplacée par un tube en cristal, portant à sa partie supérieure un petit support métallique, espèce de bague ou d'anneau. Il y a deux ou trois ans, M. Durafort a remplacé avantageusement la tige centrale par une tige en cristal évasée à sa partie supérieure en forme de petit entonnoir, le tout recouvert d'une rondelle en caoutchouc, ce qui permet la suppression de la bague ou anneau métallique. (3) La tête de siphon, ou armature, toute en métal, autrefois formée par un alliage d'étain et de plomb (ce dernier dans les proportions de 15.25 pour cent) actuellement en étain pur et régulé (sulfure d'antimoine).

La partie supérieure de la tête de siphon contient un ressort à boudin, en cuivre rouge, qui facilite le jeu du levier. Le levier est dit petit levier, ou grand levier, selon que le bouchage intérieur de la carafe se fait en dessus ou en dessous du point où l'eau gazeuse sort du siphon, pour s'engager dans le petit bec métallique de petit diamètre placé sur le côté du récipient et par lequel s'opère la vidange.

Malgré ses petites dimensions, cette partie de la tête du siphon a été longtemps incriminée comme pouvant donner lieu à la production, sur place, d'un oxyde ou d'un sous carbonate de plomb, formé au fur et à mesure du passage de l'eau gazéifiée sur les parois métalliques du dit bec.

Si, théoriquement, le fait est possible, l'observation et l'expérience démontrent que la rapidité même du passage de l'eau gazéifiée à 10, 12 et 14 atmosphères de l'intérieur du siphon dans le verre du consommateur, contrarie ou empêche même la production d'un sel plombique sur cette minime surface de contact.

L'analyse chimique vient, à son tour, mettre à néant ces appréhensions de la plumbophomanie.

Dans le laboratoire d'analyses de la société, M. Lebaigue a pris de l'eau de seltz contenue dans deux siphons à armatures métalliques, contenant dans l'alliage: la première un alliage de 30 pour cent de plomb, et la seconde une fraction d'unité 0.37 de plomb.

En analysant les deux produits, après vidange complète mais modérée et interrompue, M. Lebaigue a trouvé à la 4<sup>e</sup> décimale une très-minime différence, à savoir: 0.0007 pour le siphon contenant 30 pour cent de plomb, et 0.0007 pour celui qui en contenait moins de 1 pour cent. Il ne faut pas perdre de vue que ces deux proportions de plomb pouvaient provenir de la canalisation en plomb amenant dans le laboratoire les eaux de la ville. Du reste, sur ce point spécial, M. Durafort a réalisé un perfectionnement important en recouvrant d'une mince couche de porcelaine fine de Limoges les parois intérieures du bec du siphon. Cette couche de porcelaine se continue à l'intérieur et remplit toutes les parties vides autour de la tige centrale, et autour du piston en ébonite qui, actionné par le levier, assure le jeu du siphon.

Comme on le voit par la figure ci-jointe du premier coup d'œil, et d'une manière plus claire que par une description, avec ces ingénieuses dispositions, l'eau carbonique passe du siphon dans le verre du consommateur, sans que sur aucun point du trajet on ait à constater de contact avec l'alliage métallique de la tête de siphon. (Fig. I.)

Pour compléter cet historique, et sans me préoccuper des questions des brevets d'inventions qui sont la légitime propriété des inventeurs, et qu'ils défendront par tous les moyens de droit, je signalerai deux perfectionnements récents: l'un d'eux nous arrive d'Angleterre, l'autre est d'origine française.

Dans le new patent : Glass-lined throughout siphon head, la couche de porcelaine du siphon Durafort est remplacé par une tige en cristal d'une seule pièce dont l'ouverture intérieure se trouve à la hauteur du disque piston en ébonite qui en s'abaissant assure le jeu du siphon. (Fig. II.)

Le résultat final est le même ; couche de porcelaine, ou tube de cristal, c'est en somme le passage de l'eau gazeuse sans contact possible avec le métal.

Dans le siphon de Bordeaux l'armature métallique, ou tête de siphon, est remplacée par une tête en verre, tout en cristal et d'une seule pièce. Les seules parties métalliques (en étain pur) sont des larges bagues à l'extérieur, indispensables pour fixer la tête du siphon sur le récipient en cristal. (Fig. III.)

Le jeu du siphon se fait dans ce système par un levier agissant de haut en bas, et actionnant le disque piston qui par son abaissement favorise le passage de l'eau de Seltz sans le bec de vidanges tout en cristal.

#### IV.

##### MODES DE PRODUCTION DU GAZ ACIDE CARBONIQUE.

J'arrive à cette question spéciale ; d'une manière générale, le gaz acide carbonique  $\text{CO}^2$  pour la gazéification de l'eau de Seltz s'obtient, soit par la réaction d'un acide sulfurique ou hydro-chlorique sur des carbonates alcalins ou terreux (craie, blanc de Meudon, marbre, carbonates de soude, de chaux), soit par la désagrégation des carbonates et bicarbonates de soude au moyen de la chaleur (haute température). Les grandes fabriques utilisent le blanc de Meudon ; celles qui sont outillées avec les appareils à production demi-continue ou continue de MM. Mondollot, Herman-Lachapelle, Guéret, Durafort, etc., utilisent le carbonate de soude du commerce traité par l'acide sulfurique ou muriatique.

En 1868, Ozouf trouvait dans la combustion du coke une source plus directe de  $\text{CO}^2$ . Le gaz produit était engagé dans une combinaison alcaline laquelle décomposée à son tour par une température élevée, laissait dégager le gaz  $\text{CO}^2$ . Dans le système hollandais Bens, le  $\text{CO}^2$  est tiré du bicarbonate de soude au moyen de la chaleur élevée d'un fort bec de Bunsen.

Le gaz produit passe à travers un réfrigérant Liebig pour se rendre dans des condensateurs en fer garnis de charbon. L'embouteillage se fait dans de petites bouteilles à billes du système Codd.

Dans les appareils domestiques dits gazogènes Briett-Mondollot, le  $\text{CO}^2$  est demandé à l'action de l'eau sur l'acide tartrique et le bicarbonate de soude.

Dans ces derniers temps, M. Taquet a cherché à utiliser l'acide carbonique recueilli dans la fabrication des vins de raisin sec. Le gaz arrive dans des chambres ad hoc, où il vient saturer des carbonates du commerce.

Les bicarbonates qui résultent de cette saturation sont alors traités dans l'usine par la chaleur et fournissent un gaz très-pur.

Quelque soit le mode de production du  $\text{CO}^2$ , le gaz une fois produit et convenablement épuré est refoulé à l'aide de pompes en même temps que l'eau (préalablement filtrée) dans de récipients en cuivre, étamés à l'étain fin, où s'opère la saturation de l'eau par l'acide carbonique.

Le degré de compression est indiqué par le manomètre extérieur qui surmonte le saturateur et porté à 10, 12 et même 14 atmosphères selon le degré de la température ambiante.

#### V.

Les spécimens d'appareils pour fabrication des eaux gazeuses exposés dans la grande galerie des machines (du champ de Mars) pendant l'Exposition Universelle de 1889, ne laissent plus aucun doute sur la possibilité, et l'opportunité, d'utiliser pour la fabrication des eaux de Seltz et des limonades gazeuses, l'acide carbonique liquide.

FIG. I.—Système Duraford.

FIG. II.—Système-lined glass.

FIG. III.—Système Delorme.

Depuis les travaux et expériences de Faraday, de Pouillet et surtout de Thilorier, sur la liquéfaction des gaz, l'acide carbonique liquide dont la préparation était restée longtemps dans le domaine de la science et s'exécutait seulement, et non sans dangers, dans les laboratoires, est devenu un produit industriel à applications aussi nombreuses que variées.

L'outillage de l'usine est considérablement réduit, et la fabrication plus prompte des produits exige moins de main d'œuvre. Ceux-ci sont du reste plus agréables et plus sains puisqu'on se débarrasse, du même coup, du blanc de Meudon qui avec ses incrustations de micro-organismes donne parfois à l'eau de Seltz un goût désagréable ou nauséeux, et de l'acide sulfurique, qui malgré ses lavages répétés peut laisser à l'arrière gorge une sensation d'acreté.

L'acide carbonique liquide est incolore, mobile et remarquable par sa grande dilatabilité; son coefficient de dilatation est plus grand que celui des gaz, ce qui lui donne une force considérable, bien supérieure à celle de la vapeur d'eau.

Le litre d'acide carbonique gazeux pèse 1 gr. 529, et le litre d'acide carbonique liquide pèse 0 kil. 838. Par conséquent un litre d'acide carbonique liquide pèse autant que 548 litres 75 d'acide carbonique gazeux.

D'après ces chiffres, on voit qu'il y a grand avantage, dans la fabrication des eaux gazeuses à employer sous un petit volume une quantité d'acide carbonique répondant à un volume 548 fois plus grand que celui qu'on emploie actuellement. (Dupré.)

L'acide carbonique liquide peut devenir solide lorsqu'il est projeté sur une boîte métallique à parois minces, une grande partie se volatilise en enlevant la chaleur nécessaire à son changement d'état aux parois du vase et à la portion de l'acide restée liquide. La température s'abaisse peu à peu. Quand elle est descendue à 70° au dessous de zéro, l'acide carbonique restant se solidifie et prend l'aspect d'une neige blanche floconneuse qui a 80° au dessous de zéro.

C'est par le fait de cette propriété de l'acide carbonique liquide de se solidifier par l'action même du calorique emprunté à la partie restante par la partie qui se solidifie, que pendant le fonctionnement des bouteilles ou canons, on constate la formation de petits glaçons qui viennent obstruer l'ouverture du dégagement du gaz, surtout si l'on ne prend pas la précaution d'ouvrir petit à petit le robinet à frein qui la termine.

Ce refroidissement, au fur et à mesure que la bouteille d'acide carbonique liquide se vide, se manifeste sur les parois de la bouteille elle-même par une épaisse couche de neige.

La première application de l'acide carbonique liquide à la fabrication des eaux gazeuses a été faite à Hanovre en 1870. Petit à petit ce système s'est généralisé en Allemagne, en Autriche et en Russie.

En France, c'est seulement vers 1884 que l'acide carbonique liquide a été utilisé, en lieu et place de l'air comprimé, pour le fonctionnement des pompes à bière. Le procédé est des plus ingénieux: on commence par dégager l'acide carbonique liquide dans un tambour jusqu'à ce qu'il y ait atteint une pression de 2 atmosphères, et c'est ce tambour ainsi chargé et mis, au moyen d'un tuyau, en communication avec le tonneau à bière qui donne la pression.

Il en résulte que, durant toute la vidange, la bière est soustraite au contact de l'air extérieur; de plus, tandis qu'avec les pompes, l'acide carbonique contenu dans la bière se diffuse dans l'air comprimé contenu dans le tonneau, avec le nouveau système l'acide carbonique, que fait la pression, se dissout dans la bière, et lui donne un goût piquant en la rendant plus agréable.

Pendant les premiers temps ce produit (acide carbonique liquide) était fourni par l'usine Krupp à Essen. Il arrivait à Paris dans de forts cylindres en fer forgé dits bouteilles ou *canons*, de la contenance de 8 kilogrammes d'acide carbonique liquide comprimé à 70 et 80 atmosphères.

C'est à la séance de la Société française d'hygiène du 6 avril 1886, et à propos d'une intéressante communication de M. Mondolot sur *l'Industrie des eaux de Seltz* que M. Fichet l'un de ces vice-présidents, posa, le premier, ce point d'interrogation : Est-il possible d'utiliser l'acide carbonique liquide pour la fabrication des eaux gazeuses ?

Cette fabrication était possible, puisqu'elle se faisait depuis plusieurs années en Allemagne. Toutefois, M. Mondolot formulait, séance tenante, trois objections sérieuses : (1) " Il n'est pas logique, d'employer une force pour condenser un gaz que l'on est obligée de détendre ensuite. (2) Il est dangereux, de manier des appareils remplis à la pression de 70 à 80 atmosphères, pression indispensable pour liquéfier le gaz acide carbonique. (3) La cherté du produit le rend inabordable aux fabriques parisiennes, puisque le prix de revient d'un siphon d'eau de Seltz obtenu par l'acide carbonique liquide serait 7 à 8 fois plus élevé que le prix de revient des matières premières d'usage courant."

Malgré le bien fondé de ces objections, M. le Secrétaire Général proposa de nommer une commission chargée d'étudier la question au double point de vue théorique et pratique.

Cette étude, ajoutait-il, formerait d'ailleurs le complément logique de la question relative aux propriétés antiseptiques du gaz acide carbonique.

La commission composée de MM. Brillié, Dupré, Fichet, Moreau de Tours et de Pietra Santa se mit immédiatement à l'œuvre, et quelques jours après elle assistait à des premiers essais dans l'une des grandes fabriques de la capitale.

Ces essais furent des plus satisfaisants. Le canon de 8 kilogrammes d'acide carbonique liquide fourni par la maison Krupp fut mis en communication avec le gazomètre de l'usine ; le tirage des siphons s'effectua comme à l'ordinaire et le chiffre des siphons s'éleva à 800.

De l'avis unanime des membres de la commission, l'eau de Seltz était plus agréable au goût que celle obtenue par le blanc de Meudon et l'acide sulfurique.

Le second essai dans une fabrique moins importante porta plus spécialement sur les limonades gazeuses. Cette fois la gazéification s'effectua directement du canon d'acide carbonique liquide (surmonté d'un manomètre et muni de robinets spéciaux par l'ouverture et la fermeture. La fabrication fut très-prompote, et les diverses boissons gazeuses furent jugées de beaucoup supérieures aux produits similaires de l'usine.

Toutefois, cette double expérience, ne résolvait pas les objections de la cherté du produit, et du tribut à payer à l'industrie allemande.

Pendant que la commission se demandait, s'il n'y aurait pas moyen de recueillir le gaz acide carbonique naturel aux sources thermales de Vichy, ou de Royat, en l'emmenant, sur place et par un outillage spécial, à l'état liquide, MM. Cerckel et Fichet (de la Société des produits antiseptiques) nous annoncèrent qu'ils étaient en mesure, dans leur usine de Villers, de fournir un gaz acide carbonique liquide, chimiquement pur, produit par la combustion du coke, et vendu aux fabriques d'eau de Seltz au prix de 10 francs le canon.

Je ne saurais dissimuler la satisfaction que nous avons tous éprouvée à ce moment. En possession d'un produit avec marque de fabrique française et livré à un prix très-abordable, nous avons poursuivi avec persévérance notre propagande, toute de persuasion, en faveur de la réforme industrielle, qui représentait à nos yeux un progrès hygiénique très-notable.

## VI.

Il ne me paraît pas superflu de passer en revue les divers modes de production de l'acide carbonique liquide employés à l'étranger<sup>1</sup> et en France<sup>2</sup>.

A Berlin, la maison Kunheim a construit un établissement du même genre dont la vente journalière pour l'Allemagne seulement est de 200 bouteilles ou canons de 8 kilogrammes chaque.

A Vienne, cette nouvelle fabrication des eaux gazeuses par l'acide carbonique liquide y a été introduite par l'ingénieur Haseword. Son procédé consiste à faire réagir l'acide sulfurique étendu d'eau, et débarrassé de toutes traces d'arsenic sur le carbonate de magnésie pur. Il permet d'obtenir 450 kilogrammes de liquide par journée de 12 heures.

On applique également à Vienne le principe des compressions successives, de manière à obtenir une pression de 50 à 60 atmosphères.

L'acide carbonique liquide est alors emmagasiné dans des réservoirs en tôle dont les fonds sont soudés à leur partie cylindrique. Ces réservoirs préalablement éprouvés à 250 atmosphères contiennent chacun 20 kilogrammes du produit.

En Belgique, la Société La Carbonique de Louvain prépare en grand l'acide carbonique liquide en refoulant l'acide carbonique gazeux dans des bouteilles en fonte où il se liquéfie sous sa propre pression. Chaque bouteille renferme environ 10 litres d'acide carbonique liquide qui à la pression ordinaire fournissent 4,500 litres d'acide carbonique gazeux.

La préparation en grand de l'acide carbonique liquide permet de le produire chimiquement pur.

Les gaz provenant de la combustion de l'oxide de carbone d'un gazogène Lencauchez au coke sont lavés soigneusement pour en éliminer l'acide sulfureux et refoulés dans des appareils pourvus d'agitateurs convenables, et renfermant des solutions de carbonate de soude ou de potasse.

L'acide carbonique est absorbé, tandis que l'azote et l'oxygène en léger excès s'échappent dans l'atmosphère. La solution de bicarbonate alcalin est introduite dans une chaudière et soumise à l'ébullition par la chaleur résultant de la combustion des gaz du gazogène qui servent à la production de l'acide carbonique dilué. L'acide carbonique se dégage à l'état de grande pureté, tandis que le monocarbonate sert à une nouvelle absorption.

Le gaz carbonique est recueilli dans un gazomètre, d'où il est aspiré pour être comprimé dans un appareil à plusieurs cylindres, et amené ainsi successivement à 25 et 60 atmosphères. Il est refroidi soigneusement au sortir de chaque cylindre.

Ainsi produit, l'acide carbonique liquide est emmagasiné dans des cylindres en fer forgé (bouteilles ou canons) timbrés par une pression de 250 atmosphères, de la capacité de 12 litres environ et de la contenance de 10 kilogrammes.

Un appareil détendeur inventé par M. Froideral, ingénieur à St.-Quentin, permet de laisser échapper le gaz des bouteilles, sous une pression réduite et facile à régler. (Bulletin de la Société d'encouragement pour l'industrie nationale, séance du 22 février 1889.)

Le contenu de ces bouteilles d'acide carbonique liquide est livré aux fabricants d'eaux gazeuses à un prix qui est descendu successivement de 30 francs à 10 et même à 8 francs. Dix kilogrammes du produit suffisent à la préparation de 1,200 siphons d'eau de Seltz. Le jour où les dits fabricants auront un matériel de bouteilles, à eux appartenant, l'acide carbonique liquide pourra leur être livré à un prix beaucoup moindre.

<sup>1</sup> Le procédé employé à Hanôvre consiste à pomper le gaz CO<sup>2</sup> lavé et desséché dans une série de récipients de plus en plus petits jusqu'au moment où l'on obtient la liquéfaction à 0° et sous une pression de 36 atmosphères.

<sup>2</sup> Pour les usines françaises j'indiquerai seulement ici celui qui s'est le plus vite généralisé en raison même de sa supériorité. Dans l'usine de Villers, près Hernies (Oise), (Société des produits antiseptiques), l'acide carbonique liquide est préparé par la compression directe du gaz carbonique très pur obtenu d'une façon toute originale à l'aide d'un appareil basé sur les indications de MM. Orouf et Moisson et perfectionné par M. Gall.

## CONCLUSIONS.

En résumé, voici mises en parallèle pour la fabrication à Paris des eaux gazeuses (eau de seltz, limonades gazeuses, soda-water, etc.), la situation d'autrefois et la situation d'aujourd'hui.

Dans le passé: (1) Eaux de fabrication suspectes, imparfaitement filtrées ou plus ou moins contaminées. (2) Présence du plomb sans les armatures ou têtes de siphons; et étamage défectueux des grands appareils en cuivre de l'usine. (3) Matières premières de la fabrication plus ou moins sujettes à caution au point de vue sanitaire.

Dans le présent: (1) Eaux de source ayant séjourné préalablement dans des filtres perfectionnés. (2) Alliage métallique des têtes de siphon, exempt de toutes traces de plomb. (3) Récipients ou carafes dans lesquels, par d'ingénieuses dispositions, il n'existe plus aucun contact métallique entre le contenu (eau chargée d'acide carbonique), et le contenant (siphon en cristal). (4) Gazéification par l'acide carbonique liquide, gaz chimiquement pur, et offrant par cela même toutes les garanties désirables pour l'hygiène privée et pour la santé publique.

---

### EL BOCIO (GOÎTRE) EN LA AMÉRICA DEL SUD.

Por el Dr. SAMUEL GACHE.

*Medalla de oro en el Concurso Sud-Americano de Medicina celebrado por el Círculo Médico Argentino en 1893; Miembro de la Société Française d'Hygiène de Paris; Oficial de Academia; Delegado del Gobierno Argentino en el Congreso Internacional de Higiene y Demografía, de Paris, en 1889; Médico del Hospital Ravoson, de Buenos Aires, etc.*

Entre las endemias de la América del Sud, el bocio es una de las más extendidas.

Se ha incriminado á la naturaleza geológica de los terrenos la causa de esta deformidad, pero se ha desistido de tal inculpación en vista de los resultados negativos que muestran á aquella desarrollándose en suelos de distinto origen, y se ha buscado con más serio fundamento en la composición de las aguas, la etiología de mal tan generalizado, y así mismo su estudio en tal sentido no ha satisfecho á todos. Se ha atribuido á la falta de oxígeno, iodo y bromo en el agua; se ha pensado en las aguas en las cuales la magnesia forma el 25 por ciento del total de las sales; se ha achacado al fluoruro de calcio, etc., pero no es posible considerar estas opiniones sino como apreciaciones particulares de hechos aislados y que ponen de manifiesto resultados contradictorios, puesto que el mismo fenómeno—el bocio—se observa en condiciones esencialmente distintas.

Las aguas de nieve derretidas, dice Boussingault, se consideran por algunos como causas de coto en los que tienen que hacer uso de ellas; y efectivamente, en la Nueva Granada se observa esta enfermedad en los lugares cuyos habitantes beben de ordinario estas aguas, como sucede con los habitantes de la ciudad de Mariquita, situada en las orillas del Guali, que sale del nevado de Ruiz, con los de Ybaque que viven en las márgenes del Combeina que descende del Toluna; pero la mayor parte de los pueblos en donde el coto es endémico estan sin embargo muy distante de los nevados, y las aguas que en ellos se beben no provienen de la nieve derretida. El autor ántes citado, refiriéndose á sus observaciones verificadas en aquel país, dice que no conoce bien allí sino dos lugares donde los habitantes beben exclusivamente agua de manantial, y son Nemocón en la provincia de Bogotá, que posee un abundante manantial que brota de la piedra arenisca, y la ciudad del Socorro, cuyos habitantes beben aguas de manantiales que salen de la roca caliza. En esta última los cotos son muy comunes y voluminosos, y en Nemocón no observó uno solo.

Tenemos pues dos hechos: las aguas que corren por rocas de cuarzo insolubles no ejercen acción ninguna sobre la glándula tiroides, y los individuos que beben el agua que sale de una roca caliza, soluble en parte por el ácido carbónico que contiene, ven esta glándula hipertrofiarse y llegar á un desarrollo enorme. Y de aquí nace el problema de si la naturaleza de los terrenos que las aguas cruzan tiene ó no, influencia en el aumento de la tiroides; problema que muchos autores han resuelto, estableciendo después de sérios estudios que, con escepción de las rocas calizas, la naturaleza del suelo no parece ejercer influencia alguna sobre la frecuencia de los cotos, y que esta influencia, si efectivamente la hay, no se extendería sinó á los lugares en donde existen las rocas calizas secundarias, siendo así que en la mayor parte de los lugares en donde el coto es endémico no hay rocas calizas.

La suposición de que el agua al salir de los nevados ó de las altas montañas produce cotos en los que las injieren, y que esta propiedad la pierde cuando se aleja de las fuentes y gana el aire que necesita, se rebate con el hecho de que en lugares bajos y en donde no se emplean las aguas procedentes de las montañas, el coto es, sin embargo, constante, y hasta muy común; pudiendo mencionarse poblaciones importantes en las que se beben aguas que por su origen contienen poco aire, y en las que sólo por excepción se encuentra el bocio. Boussingault refiere que estos últimos hechos han sido comprobados en lugares poblados por Indios, raza que parece exenta de cotos en donde quiera en América; por lo menos, dice, yo nunca he visto indio de raza pura con coto.

En Coloya, en Piedras y en las orillas del Combeyma, abundan los cotos entre los negros, mulatos y mestizos, y los Indios están exentos aunque usan de las mismas aguas. Antes que yo, un célebre viajero había hecho la misma observación. Los indígenas de tez bronceada gozan (dice M. Humboldt) de una ventaja física que depende sin duda de la sencillez del género de vida de sus antepasados por millares de años. Jamás he visto Indios corcobados, y raramente se ven Indios bizcos, cojos ó mancos. En los lugares en donde los habitantes están sujetos á cotos, los Indios carecen absolutamente de esta enfermedad, que se vé pocas veces aún en los mestizos.<sup>1</sup>

En concepto de Bordier, los Indios están en los Andes sujetos al bocio; los mestizos lo son menos; vienen en seguida los blancos, en fin los negros; y como, se vé, estos datos difieren de los anteriores. La observación local nos demuestra lo mismo que ya Boussingault había notado. Los Indios Quichuas de Iujuy permanecen inmunes; y esto está en oposición con lo aseverado por Bordier. Los estudios de Grange ilustraron en su época este punto oscuro de la etiología de la endemia de que hablamos, y llamaron la atención sobre la circunstancia de que en todos los valles en donde ella reina, las aguas potables, sea cual fuere el terreno por donde corren, contienen una fuerte cantidad de cloruro, sulfato, y carbonato de magnesia. A su modo de ver, es la falta de cal en las aguas abundantes de magnesia lo que causa el coto y propone hacer pasar las aguas nocivas por filtros ó depósitos llenos de cal carbonatada ó de una capa delgada de cal. El estudio químico de las tierras de las regiones bociógenas, parece igualmente, según autores varios, no dar mucho fundamento á una teoría para encontrar en sus componentes el origen de la enfermedad en cuestión, pero, á nuestro modo de ver, este estudio merece recomenzar, y tal vez algun día se le llegue á asignar mayor influencia de la que hasta hoy se le da. En la acción de algun elemento especial de estas tierras sobre las aguas que las cruzan, ¿no podría fundarse una sospecha que contribuyera á explicar la génesis de los trastornos que nos ocupan? El exámen bacteriológico de dichas tierras prodría iluminar el punto, determinando la clase de germen que obra en estas condiciones.

Rechazadas las teorías que se han dado para fundar más ó menos científicamente la etiología que buscamos, y reconocido con Baillarger que existe un agente tóxico, especial, único, siempre el mismo, que afecta los organismos vivos y les imprime

<sup>1</sup> Boussingault, Viajes, etc.

un sello de degeneración siempre idéntico, cuyo primer grado es el bocio y el último el cretinismo, debía irse á la investigación de este agente para comprobar la manera de pensar de Arnould sobre si su causa reside en algunos de los elementos conocidos del agua ó en algún otro desconocido aún. Podrá tal vez, según este autor, referirse al parasitismo, y entonces se reconocerá en aquella la bacteria bociosa. Y así ha sucedido, en efecto. Poco tiempo después de las previsiones del sabio francés, los Dres. Lustig y Carle publicaban los resultados de sus estudios hechos con aguas del Valle de Aosta, donde el bocio es endémico y establecían las siguientes conclusiones: (1) Todas las aguas examinadas que sirven para beber y para los empleos domésticos á los habitantes afectados de bocio endémico, son muy ricas en bacterios. (2) Presencia constante en cantidad variable de un bacilo que licua la gelatina con caracteres morfológicos y biológicos especiales. (3) Los experimentos de hacer beber esta agua, en un territorio exento de bocio, á los caballos y á los perros sanos han demostrado que el agua tiene el poder incontestable de producir un aumento del cuerpo tiroides. (4) No está aún probado que la eliminación de los microbios quite la propiedad bociógena.

La etiología del bocio viene así á quedar bien establecida y confirmada la previsión de Arnould, por la aplicación de la teoría microbiana. La bacteria se encuentra ciertamente en el agua, pero hay que averiguar si esta agua se limita simplemente al rol de vehículo, arrastrando al germen que toma del suelo, ó si la bacteria reconoce otra procedencia. Muy posible es que la verdad se encuentra en la primera de estas suposiciones. ¿No es en el suelo donde germina el bacillus *malariae*? ¿Porqué no podría también originarse en él el microbio del bocio? Y decimos que probablemente la bacteria se origina en el suelo, fundados en este hecho; las aguas bociógenas no lo son en toda la extensión de su curso; y puede establecerse el principio y el fin de su acción. En otro tiempo se atribuía gran valor etiológico á la herencia en primer lugar, la genitalidad, la altitud, etc. Muy posible es que todas estas circunstancias coadyuven á despertar la enfermedad, preparando el terreno que la bacteria más tarde ha de fecundar; pero ante todo hay que reconocer la acción directa de esta última, cualquiera que sea su punto de origen. Bordier que ha estudiado especialmente estas cuestiones de geografía médica, dice que el bocio se encuentra sobretodo en las montañas y en los países fríos como en los países cálidos, siendo la condición dominante, la permanencia en las montañas. Tal proposición no es del todo exacta por lo que se refiere á la República Argentina, pues vemos el bocio desarrollarse tan pronto en comarcas montañosas como las Provincias de Cuyo y las de Tucumán, Salta y Jujuy, como en la de Corrientes, imponente por su llanura, cubierta de vegetación. Si él reina en las primeras á título de ser en ellas montañoso el terreno, ¿cual razón se invocaría para justificar su presencia en la otra, situada lejos, muy lejos de las montañas?

No puede argumentarse que la menor frecuencia de su invasión en Corrientes probaría la influencia de la altitud, porque si bien hoy allí ataca un número relativamente reducido, en cambio antes de ahora ha hecho muchas víctimas. En ciertos pequeños pueblos de Corrientes, sobre el río Uruguay, se han encontrado en otro tiempo muchos bociosos que parece habían contraído su afección á causa de beber agua del pozo, en lugar de usar de aquel río, infinitamente superior. Es evidente su disminución en esta provincia, y no es posible atribuirla á modificaciones operadas en las condiciones generales del terreno, ni en la vegetación, ni en las aguas. ¿Es que algun foco ignorado se habrá destruido? Más aceptable nos parece la acción del intercambio de las razas que sufren nuestros pueblos del litoral, á los que el extranjero acude con preferencia llevando con su sangre nuevas fuerzas, mayores aptitudes para la lucha y hasta más vigor para resistir al ultraje del clima y á las vicisitudes propias de cada país. ¿Y por qué San Juan, rodeado como Mendoza por los Andes, ha desterrado el bocio? Y San Luis, en las mismas

condiciones, ¿por que tampoco lo tiene, mientras que aquella le paga tributo abundante? Es que hay algo más que la influencia de la altitud en la producción de estos hechos. Y ni siquiera puede invocarse aquí la falta de aereación del agua por que cuando llega á ingerirse ha recorrido trayectos de muchas decenas de leguas.

Su condición más favorable es sin duda alguna la permanencia en país de montaña, siendo elementos que entran en esta condición las distintas circunstancias y agentes climatéricos, debiendo recordarse la influencia de la vegetación, la del suelo considerado en sus componentes especiales, y muy principalmente la de las aguas que cruzan terrenos de diversa constitución, que tienen en disolución ó en suspensión principios minerales tomados de ellos y que conviene estudiar en cada punto. En nuestro país no se origina únicamente en las provincias cuyo territorio está cruzado por montañas, y así es que se presenta en poblaciones muy distintas de ellas y en las que no hay que tomar en cuenta la altitud, que es insignificante y sin valor alguno. Esta condición no es primordial pues en la producción del bocio, si bien ella actúa y se le reconoce en los parajes donde la endemia ataca. Veamos entre tanto cual es su frecuencia en nuestro país. En Mendoza abunda el bocio; y su mayor número se encuentra en las mujeres. En 1879 había en la ciudad 245 de estas con bocio y 65 hombres. Existe en esta provincia, á corta distancia de su capital, un paraje denominado San Vicente, donde esta enfermedad es tan común que entre los habitantes del resto de la misma ha llegado á ser proverbial la calidad de Vicentino ó cotudo, sinónimos para muchos. Cualquiera que haya pasado por dicho punto ha podido cerciorarse de la enorme cantidad de estos infelices. En todas las secciones de su territorio se encuentran de ellos, y su relación oscila, según el Dr. A. Lemos, entre 8 por cada 100 habitantes como en San Vicente, y 1 por cada 100 como en Luján, correspondiendo como término medio á San Martín y la ciudad, 3 por 100. Talvez sea exagerada dicha proporción por lo que respecta á esta ultima; pero no lo es seguramente para los departamentos nombrados. Así pues, Mendoza vendría á estar en igualdad de condiciones que muchos departamentos de Francia, donde la proporción de bociosos es de 7.3 por 100 habitantes, y en otros es de 3 por 1. En todo este país (Francia) se estima en 500,000 los que padecen dicha deformidad. En San Juan vá desapareciendo al extremo de ser raro encontrar de estos individuos. En San Luis se le vé escepcionalmente. El contraste que ofrecen las Provincias de Cuyo es notable; muy frecuente la endemia en Mendoza, casi nula en una y nula en la otra, siendo así que en todas ellas se encuentra la influencia de la altitud, la vegetación, las aguas abundantes y hasta la ausencia de elementos extranjeros en una población, cuya mezcla con el nacional daría por resultado una modificación en el tipo, que será favorable á la extinción de la enfermedad, por cuanto produciría enjendros menos aptos para su desarrollo. En cambio, al norte de la república el bocio asume proporciones alarmantes, y en Guachipas ni el cura ha escapado á su invasión. En Tucumán se le encuentra preferentemente en la capital (al sur) y en sus alrededores: Tafi, San Javier, Yerba Buena. Además se le vé en Lules, Faimallá, Monteros con frecuencia, como así mismo en Trancas, San Pedro de Colalao, Graneros, Chicligasta y Río Chico. En la zona correspondiente á los valles Calchaquies no se ha observado la enfermedad. La Provincia de Salta tiene regiones donde el bocio constituye un verdadero azote y su mayor contingente lo suministran los departamentos de la Capital, Cerrillos, Caldera, Chicoana, Rosario de Lerma, Guachipas y Campo Santo, es decir que es la comarca comprendida en el Valle de Lerma la que más tributo paga á la endemia, existiendo algunas de estas poblaciones donde la mitad de sus habitantes la padecen como Calderilla, por ejemplo. Güemes y Santa Rosa son fuertemente atacados.

La ciudad ofrece numerosos ejemplares diseminados en todas las esferas sociales; y á estar á lo referido por el Dr. Niño, esta enfermedad no remonta aquí á épocas lejanas, sino que es de data reciente comparada con la antigüedad que ella

tiene en el resto del territorio. Y en su concepto hay que buscar la explicación en modificaciones que se han producido en las aguas del Río Arias, de las que se surte la población. Según el Dr. Niño, este río, á consecuencia de crecientes anteriores, ha engrosado su caudal con las aguas del de la Silleta, que, abandonando su cauce vino á confundirse con el anterior; desde entonces el coto hizo su aparición en la capital. No hay duda al respecto, pues en la epidemia de cólera de 1886-87 se pudo comprobar que, con motivo de usar los habitantes el agua hervida, los bócios disminuyeron de volúmen, al mismo tiempo que las fiebres intermitentes dieron tregua á sus invasiones. De esto se deduce fácilmente que el último de estos ríos contiene algún principio ó gérmen mórbido que por su acción sobre el organismo produce la endemia. Y dá más valor á esta hipótesis el hecho averiguado de que los más acabados ejemplares de bócio los produce la sección de la Silleta. Corresponde pues averiguar la composición de las aguas del río de este nombre, hacer su exámen bacteriológico para encontrar en ellas el origen ó causa de la endemia. Si el hecho anotado es evidente, como lo suponemos, y si es cierto que ántes de confundir sus aguas los mencionados ríos no se conocía en la ciudad de Salta la enfermedad en cuestión, resalta la urgente necesidad de buscar en las del primero y en las tierras que cruzan, las causas del mal.

La bacteriología tiene que ilustrar el punto, y es ella la única que podrá decidir en última instancia con verdadero criterio fundado en la demostración práctica, la verdad de estas apreciaciones que hoy por hoy tienen para nosotros mucho de positivo. En la Provincia de Jujuy se encuentra el bócio en los departamentos siguientes: San Pedro, Perico, parte meridional del Valle Grande y Ledesma, siendo el último el más atacado. Resulta que la enfermedad reina en las poblaciones inmediatas al Río Grande. Se ha comprobado una marcada tendencia á disminuir. En la Provincia de Catamarca, la región bociosa, la componen la capital, Piedra Blanca y Poman, en el último de los cuales desaparece el río Belén. Los otros dos departamentos están regados por el río del Valle que muere en Capallán. Andalgalá y Belén son también muy visitados por la endemia. El Dr. de la Vega piensa que la consanguinidad es un factor importante que entra en la etiología del bócio en esta Provincia (Catamarca).

La proporción entre hombres y mujeres bociosas es de 1 de los primeros por 10 de las segundas. En la mujer que no ha tenido hijos su marcha es lenta, en tanto que en la múltipara es bastante rápida.

Se ha notado hácia el sur del Valle de Catamarca, en el borde del gran Río Salinas, que en varias estancias existen pozos cuyas aguas, ligeramente saladas, tienen la propiedad de hacer desaparecer la hipertrofia de la glándula tiroides después de algunos meses de uso, y con tal de que esta no sea muy considerable. Se supone que estas aguas contienen iodo y bromo, pero ningún análisis seriamente practicado ha puesto de manifiesto la presencia de estos metaloides. En la Provincia de la Rioja, solo en un pequeño pueblo del Departamento de Chilecito, en un fondo de valle y cuyas aguas son como la mayor parte como las de la región calcarea, se vé el coto y con frecuencia. Existen en ese punto familias enteras de cotudos que se entrelazan con individuos de otras también cotudos, dando frutos de la misma clase. Hay que agregar que familias que han ido á vivir en ese paraje han permanecido inmunes y lo mismo sus hijos, lo que podría ser un argumento en favor de la herencia, si hechos bien comprobados no demostrasen que individuos libres de toda herencia son víctimas de la endemia, lo que es de observación corriente. La disminución de la hipertrofia de la glándula tiroides con la salida del paciente del punto y su nuevo aumento con el regreso á dicho paraje, ha sido igualmente objeto de serias investigaciones que así lo han demostrado.

El bocio ataca á los animales; y así se ha visto en Tucumán perros y caballos con esta deformidad. Reduciendo su frecuencia en la República Argentina bajo la forma de un cuadro, según los datos del censo de 1869, resulta:

| Provincias.               | Altura<br>sobre el<br>nivel del<br>mar. | Número<br>de<br>bociosos. | Provincias.     | Altura<br>sobre el<br>nivel del<br>mar. | Número<br>de<br>bociosos. |
|---------------------------|-----------------------------------------|---------------------------|-----------------|-----------------------------------------|---------------------------|
| Buenos Aires .....        | 15                                      | 38                        | Mendoza .....   | 777                                     | 1,712                     |
| Sante Fé .....            | 20                                      | 18                        | San Juan .....  | 704                                     | 64                        |

| Córdoba .....             | 416                                     | 135                       | Tucuman .....   | 450                                     | 605                       |
| Santiago del Estero ..... | 162                                     | 47                        | Salta .....     | 1,115                                   | 1,150                     |
| San Luis .....            | 766                                     | 58                        | Jujuy .....     | 1,227                                   | 535                       |

Del total de bociosos corresponden: 1,701 al sexo masculino y 3,500 al femenino. Tales son los datos en que se fundan nuestras apreciaciones; pero hay que hacer constar que hoy el bocio desaparece notablemente en muchas provincias, si bien se conserva en otras. En Tucumán, donde en épocas anteriores era acompañado de cretinismo y que obligó á la población á abandonar su asiento sobre el río del Pueblo Viejo por el que actualmente ocupa, se comprueba su disminución. En Jujuy disminuye igualmente, y esto es debido en mucha parte á las epidemias de viruelas que azotan amenudo á los indios. Además, influyen para producir este buen resultado el mayor cuidado que la gente pone en el aseo corporal, en la difusión de los conocimientos higiénicos que previenen las enfermedades y también en la mezcla de la población con individuos llegados de diferentes regiones.

Faltan observaciones que demuestren el tiempo necesario para el desarrollo del bocio en nuestro país pero se sabe que algunas fuentes del viejo mundo lo dan en 15 días, y que la residencia en puntos frecuentados por la endemia puede producirlo en algunas semanas particularmente en individuos no aclimatados. Y á este respectó cita Bordier los hechos siguientes: En Clermont, en 1851 sobre 5,635 soldados hubo 180 bociosos; en 1874 en Saint Étienne, sobre 1,400 hombres, 280 la contrajeron; en Colmar en 1864 sobre 600 individuos 107 fueron atacados, y en Annecy hubo 128 sobre 682 personas.

Haremos ahora algunas consideraciones sobre ese estado que acompaña frecuentemente al bocio, el cretinismo, verdadera degeneración de la especie, último término adonde llegan las consecuencias de la endemia. Etiológicamente considerada, la degeneración reconoce como factores principales el clima, el suelo, la alimentación, las enfermedades, y se deben citar también las causas sociales, los matrimonios consanguíneos, la falta de intercambio con individuos de otros pueblos y otras razas, para producir la renovación del tipo y darle nuevas aptitudes. Todas estas causas son bien conocidas y sus efectos bien determinados para que las exponamos detenidamente. Pero conviene recordar que los climas obran distintamente sobre el organismo, lo impresionan de manera desfavorable muchas veces, y lo predisponen á los padecimientos. El brasileiro se queja de frío en el verano de Buenos Aires, con nuestra elevada temperatura; y mientras el invierno es aquí muy crudo, el Paraguay ofrece agradable y templada atmósfera. El invierno en Chile es tan fuerte que obliga á los individuos á hacer uso excesivo de los alcohólicos, y de ahí la crecida cantidad de hepáticos que ofrece la patología de nuestros vecinos. El clima del norte de la República Argentina impresiona mal al forastero, y le invade el chuco; y si tenemos localidades como Rosario de la Frontera y Puente del Inca muy apropiadas para la cura del reumatismo, y Cosquín, Mendoza y Luján,<sup>1</sup> puntos especiales para residencia de tuberculosos, lo cual se dice también de Corrientes, en cambio Buenos Aires ofrece ancho campo á estas enfermedades y ataca gran número, sin olvidar por eso la fiebre tifoidea, la difteria y otras que están radicadas en nuestra capital.

Hemos dicho que el bocio y el cretinismo tienen estrechas relaciones, como que el segundo es un estado que obedece á causas de degeneración que obran crono-

<sup>1</sup> Lujan, Provincia de Buenos Aires.

lógicamente encadenando sus desastrosos efectos que se trasmiten por herencia, y cuyo comienzo se encuentra en el primero de aquellos como manifestación patológica. Y esa relación es tan evidente que no escapa á la observación vulgar. La Provincia de Mendoza, con su enorme cantidad de bociosos, ofrece crecido número de cretinos (talvez 100), particularmente en San Vicente. Y si bien en las regiones donde el bocio reina entre nosotros se comprueban todas las formas, es la benigna la más común. Es absolutamente imposible presentar datos exactos, siendo el censo de 1869 el último que se practicó, se comprende que hoy se carece de base fija para apreciar los hechos. Sin embargo, hemos querido dar una idea al respecto, consignando lo que se sabe sobre el particular. En Bolivia abunda el bocio. La región oriental es la que más favorecida es por la endemia, especialmente la parte comprendida entre el Río Grande y Santa Cruz. En el Sud, es Tarija la más atacada, al extremo de que en los puntos elevados que ocupan considerable extensión de la zona más poblada del país como son Potosí, Sucre, La Paz, Cochabamba, etc., el calificativo de tarijeño es sinónimo de cotudo, lo mismo que hemos visto que ocurre entre nosotros con los cotudos de San Vicente (Mendoza) llamados por equivalente vicentinos. Todos los valles son centros de producción de la endemia; en las mecetas ó altiplanicies es desconocida, pero la contraen los individuos que habitando en ellas descienden á las vegas. Los naturales del país atribuyen el origen de la enfermedad á un árbol denominado Alizo, que crece en las orillas de los ríos, y es común entre los indios y gentes del pueblo la suposición de que cuando se inclinan para beber en dichos ríos, si el árbol les dirige la palabra, quedan ya condenados á arrostrar las consecuencias de la afección.

Se ha observado que en la ciudad de Sucre, adonde antes no había coto se le encuentra hoy, y su presencia ha coincidido con un estado particular de las cañerías de barro por donde corren las aguas de consumo. Estas cañerías se han encontrado sucias, con depósito de materia orgánica. En el Perú, en la hoya de Vilcamayo, es endémico el bocio; y el cretinismo lo acompaña amenudo. En el Paraguay es frecuente igualmente el coto, sobretodo en Villa Rica; y en la Asunción se le encuentra en todas las clases sociales, siendo de advertir que tal vez estos cotudos procedan de la campaña. En México existe en el Pueblo de Santiago Tuxtla, Huichapán, Huejutla, Michoacán, Guerrero y Sinaloa.

No queremos terminar sin hacer mención de las opiniones manifestadas últimamente en el Congreso de la "Association française pour l'avancement des sciences" (session de Pau, 21 septembre 1892) en el que Chopinet (de Lérrouville) ha expuesto sus ideas sobre esta cuestión y presentado las siguientes conclusiones:

(1) Es en el fondo de los valles, en la proximidad de los arroyos que se observan casi exclusivamente estos dos síntomas de una misma enfermedad (bocio y cretinismo). (2) La endemia crece de intensidad, desde el origen de los valles á los últimos contrafuertes de la cadena. (Pirineos.) (3) La endemia tiende á atenuarse de una manera general; ha desaparecido de varias localidades en otro tiempo muy afectadas. Este retroceso de la enfermedad no puede atribuirse á un cambio en la naturaleza de las aguas de bebida, sino á los progresos del confort y de la higiene general. (4) En la constitución geológica del suelo, los sitios esquistosos gozan incontestablemente un rol perjudicial. (5) Las causas muy numerosas del cretinismo y del bocio son en los Pirineos, la humedad y la suciedad de las casas, la falta de aereación y de luz solar, la mala alimentación. (6) En los Pirineos, no hay sino la doctrina de las causas múltiples del bocio, que no sea desmentida por los hechos.

En el mismo congreso, Gils ha referido el origen de esta enfermedad á un microorganismo, diciendo que puesto que ella ha podido aparecer momentáneamente y desaparecer en seguida en medios en que antes era desconocida, es lógico atribuir su causa á un principio viviente, susceptible de adquirir y de perder su carácter

nocivo; con lo que el bocio entraría así en la clase general de enfermedades producidas por micro-organismos y podría bajo ciertas influencias extenderse y propagarse por la invasión de estos.

Las cuestiones de terreno ó de composición de las aguas en los países de bocio se reducirían según Gils á una cuestión de medio de cultura, propio al desarrollo del micro-organismo; y en estas condiciones la afección no aparece más como fatalmente inherente á una región, y que sólo puede modificar una revolución geológica sino más bien una infección de medio, de la cual la higiene debe triunfar. La teoría microbiana aplicada á la etiología del bocio gana terreno y se confirman así las previsiones de Arnould.

#### RESÚMEN.

(1) El bocio es endémico en muchos países de la América del Sud. (2) La causa de la endemia es un micro-organismo, según las últimas investigaciones. (3) Los elementos del suelo en las regiones de bocio, deben ser convenientemente estudiados. (4) En la República Argentina, el bocio es endémico en las provincias montañosas pero en algunas de estas mismas va desapareciendo. (5) En la provincia de Corrientes, en la parte sobre el alto Uruguay, regiones de llanura, también se le encuentra entre los naturales, aunque no es abundante. (6) En las Provincias de San Luis y San Juan, disminuye notablemente; y en Mendoza, en las mismas condiciones que estas, su frecuencia es muy crecida. (7) En Salta también es muy frecuente. (8) Hay fundamento para suponer que en la República Argentina el bocio tiende á extinguirse en los focos donde hoy la población se mezcla con otras razas y otros tipos. La influencia del intercambio de la sangre parece evidente.

#### A BRIEF CONSIDERATION OF ELEPHANTIASIS ARABUM AS OBSERVED IN THE SAMOAN ISLANDS.

By JOHN C. WISE, M. D., Surgeon U. S. Navy.

While this disease does not present itself for the practical study of the medical profession from a scientific and humanitarian standpoint, it must claim our attention. The nomenclature and etiology are involved in a myth of terms and theories insomuch that any contribution in that direction would seem desirable. Aitken long ago deplored the tendency to give to the same pathological condition names varying with the locality or based on some anatomical feature. Much of this is unavoidable, much might be obviated, but until pathology is more exact pathological conditions will continue to be inexactly named. The disease under consideration has been known as "Barbadoes leg," "Egyptian sarcocoele," "lèpre tuberculeuse éléphantine," "hernie charnue," "elephas pachydermia," "bucnemia," "hypersarcosis," "febris erysipelatosá," and "elephantiasis cruris." The earlier name is probably the best, having at least the negative advantage of giving no erroneous theory as to the nature of the malady. Elephantiasis Arabum is a constitutional disease characterized by paroxysmal fever, erysipelatos and hypertrophic inflammation of the skin; at first local, but invariably progressive. The condition is attended by the presence of a nematoid in the blood, probably the *filaria sanguinis hominis*. The etiology of elephantiasis is still *sub judice*. It is par excellence a disease of hot and damp climates; humidity and heat being the most important factors in its production. The inhabitants of islands and theseacoast are the chief sufferers, and it has been argued from this that a fish diet causes elephantiasis. Inasmuch as the majority of the insular population do not suffer, this proposition can not be accepted. Furthermore, the Samoan islanders are inexperienced fishermen, and fish forms a small part of the diet, yet the number of cases in the islands is un-

sually large. Common to both sexes, the disease occurs much more frequently in the male, and is unusual in interiors. The dark races are its victims, and it has been asserted that no case occurring in a person of unmixed white blood has been noted. This statement is an error. At Samoa a Swede, resident of the islands since the American civil war, had well-marked initial hypertrophic disease; but most of the whites attacked have a strain of native blood. The white race escapes in virtue of non-heredity and an entire difference in the mode of life. The strongest evidence of race and climatic influence is afforded by the fact that the disease in its earlier stages can be eradicated by removal from the endemic locality. There is an undoubted hereditary influence, and mildly contagious characters are probable. Of 737 cases reported by Richardson, 236 had one or both parents affected. Of two families living under the same conditions and in proximity, one has the disease and the other is immune. If we consider the manner of Samoan life, many persons sleeping on the same mat, and all eating from one bowl, and further, if we reflect on the prevalence of ulcers other than elephantine, and the secretions from the skin of those who do suffer, we must conclude that most facile conditions for contagion exist. The most diverse evidence is offered as to the influence of malaria. Osgood (Foochow) states that in 57 cases a malarial history was traced in all. Heffinger (U. S. Navy), on the other hand, calls attention to the fact that in Samoa, where elephantiasis is endemic, malarial fevers are never seen, and his observations are sustained by other naval medical writers. There can be no doubt that secondary and local causes are more important than has hitherto been supposed. Heffinger (U. S. Navy) attributes much influence to the custom of sitting and sleeping on the damp floors of the native houses. The writer observed in all cases occurring in the lower extremities that the soles of the feet were deeply cracked and ulcerated, the result of walking barefoot along the stony shores and pathways. Over 50 per cent of the islanders are so afflicted, and it is in their belief a cause of hypertrophic disease. A Swiss resident in the islands since the American civil war had well-marked evidence of commencing disease, which he felt assured he could combat successfully if furnished with shoes. A half-caste (Tahitian-English) informed me that his case commenced with wounds of the feet. It is probably not in the remote future when scientific methods applied to the study of this disease will reveal its true nature. Richardson (British India), 1877, discovered two living specimens of filariæ in the diseased tissue of a Bengalese suffering from scrotal elephantiasis. Bancroft (England) later found filariæ in the lymphatic abscess of the arm associated with embryonic filaria in the blood. There is an unascertained relation between these discoveries and those of Bilharz (at Cairo) in 1851, of Wacherer (Bahia) in 1861, and of Crevaux (French Navy) in 1870, who found nematoidea in the urine of a creole suffering from chylous hæmaturia. Lewis has traced the filariæ to the blood in fifteen instances, each suffering from chyluria or some kindred affection. It is probable that the non-venereal adenitis of Samoa is of this origin. These nematoidea entering the blood and later the lymphatics, predispose to inflammatory changes in the latter system. Agnew (*op. cit.*) observes that the most plausible view of the disease is that which regards it as a lymphangitis. Authorities have variously attributed the diseased condition to an inflammation of the arteries, veins, lymphatics, and skin. In an advanced case there is an involvement of all these parts. Observations of 100 cases in Samoa affecting the lower extremities showed lesions of the feet followed by inflammation of the lymphatic vessels. Virchow has called attention to the lymphatic vessels especially, and considers the hypertrophy due to this vascular hyperplasia; the veins and arteries become involved secondarily, the lymph spaces are engorged, the meshes of the areolar tissue are filled with plastic exudates, the normal elements of the part take on increased activity, a dermatitis is set up, and the absorbents unable to remove the extensive deposits, enormous

edema and hypertrophy result. In the earlier cases in many instances the red line of the inflamed vessel may be noted, while later they become knotted and corded. Clinically, the following features are noted: There is pain, heat, redness, and all the signs of inflammation; often this condition is found along the course of the lymphatics. Preceding or accompanying this local manifestation there are fever and general disturbance, varying greatly in severity. Elephantiasis as observed in Samoa is peculiar in the absence in a majority of cases of general symptoms, the local condition being painless, though rapidly progressive. In cases where it occurs the fever and general symptoms subside to return again and again, leaving the tissues more swollen and indurated after each attack; eventually a chronic inflammation of the skin and cellular tissue results, and hypertrophic changes progress rapidly. The skin, enormously infiltrated, disposes itself in overlapping folds, the papillæ are enormously enlarged, forming a verrucose variety, or eminences of a tuber-like shape, elephantiasis tuberculosa; the vascular coats being involved, a nævoid variety results. The overcharged skin is in a moist or weeping condition and a lymph-like fluid escapes. Pain is not a late symptom, anæsthetic symptoms then prevailing. Often the inflamed lymphatic glands enlarge and break down in ulcerous masses. A systemic condition followed by local irritation, affecting primarily and principally the lymphatics, are thus the essential features of this disease. Little of value can be said as to treatment. The natives practice a rude massage, and are aware of the benefits arising from protection of the feet and the uses of compression. In an intelligent half-caste good results quickly followed the use of an iodine liniment and compression by a roller where the part affected was in the lower extremities.

The Samoan Islands have been considered a center of dispersion for the population of the Pacific, and inasmuch as the natural disposition is to the contrary the theory seems well founded. We are aware that the strongest arguments in favor of the descent of our American Indian from Asiatic ancestors rests on the fact of Japanese canoes having been found on the west coast of North America, carried thither by the "Kuro-Siwo" or Black Stream of Japan. Now, in the region we are considering, that is, from 30° south to 30° north of the equator, the conditions are all unfavorable to migration from east to west. Not only does a strong equatorial current prevail, but the trade winds are a powerful impediment to even steam navigation. Winds do change for a period, a kona or southeast wind prevailing at times for weeks, alternating with calms, and it must have been in these intermissions that migrations from the eastern to western islands were feasible. Canoes have recently been found wrecked in Kauai, a northern island of the Hawaiian group. The Samoan belongs to the Maori branch of the Malayan family, the islands having probably been peopled from Australia, and from Samoa the islands to windward have received their earliest settlers. It is easy to establish a relation between the Samoan and Hawaiian from the language and customs alone, which are closely allied. The life history of these two groups, the Samoan and Sandwich (Hawaiian) islands, is a most interesting problem. Of the same origin, inhabiting insular homes, much alike in climate and production, why has the one maintained itself and the other almost perished? It would seem to be but an illustration of the law that when the white and dark races are in continued contact the latter sooner or later succumbs. Cook estimated the Hawaiian people at 300,000, a rude estimate, of course. But those who till the uplands of Hawaii to-day to plant their coffee come upon the foundations of what were extensive villages. The census of 1832 gives a population of 130,315; the last one gives 47,508, while to-day it is believed there are not over 25,000 islanders. It is believed that in another quarter of a century this people will have entirely disappeared. Cook's crews and those of successive voyagers implanted syphilis; leprosy was brought in from China; later, epidemics of smallpox and measles of unusual virulence rav-

aged the islands. The introduction of alcoholic liquors was a serious cause of national decay. From all accounts the Hawaiians were at all times highly immoral; polygamy, polyandry, abortion, and infanticide were natural vices. But these factors were more than counterbalanced by the vigor of the race in Cook's time. He found them of fine physical proportions, amiable, but given to war and gymnastic sport. The Samoan people were fortunate in being out of the route of trade. Unlike the Hawaiian islands, the Samoan group was rarely visited, and only in our day is a knowledge of the people being obtained. These facts and an unusual chastity observed by the women in their relation to foreigners has so far preserved them. Yet about Apia, where the whites are increasing, the natives are, on the contrary, diminishing. Statistics of the group are wholly unreliable. In 1840 the population was given as 56,000; in 1870, 35,000; in 1880, 30,000. There can be no doubt that the constant tribal warfare, fomented and continued by foreign interference, has prevented a growth which the vigor of the race would justify. The tax-gatherers of King Laupepa, sent from Opolu to the other islands, had no knowledge of the number of the King's debtors. The birth rate is high and there is a great love of children among the Samoans. With peace and non-interference the race would be physically a prosperous one.

---

#### ON SOME PECULIAR DISEASES ENCOUNTERED IN NAVAL CRUISING AND RECENT OBSERVATIONS ON HAWAIIAN LEPROSY.

By GEORGE W. WOODS, M. D.,

*Medical Inspector, U. S. Navy, in charge of U. S. Naval Hospital, Mare Island, Cal.*

In these days of almost perfect hygienic surroundings on board an American man-of-war—the issuing of rations which could scarcely be improved, embracing fresh provisions, either canned or supplied from local markets, furnished in abundance and variety, the use of distilled water or that of undoubted potability, the careful medical supervision of our crews both ashore and afloat with reference to diet, clothing, and climatic or morbid exposure—we have few diseases introduced on board ship, and those which are embraced under the title of strictly demographic diseases and distinct from climatic are practically unknown as affecting our officers and enlisted men. But though thus defended from contagion or the action of demographic influences, the diseases peculiar to the countries visited by our ships on foreign stations have been made a subject of earnest study by the medical officers of our own and other navies, while their investigation and practice have been productive of marked results by adding to the sum of knowledge of obscure and recondite disease and in the extension of philanthropic care to sufferers in the far-away coasts and islands reached by our ships, where no intelligent and skillful attention is otherwise to be obtained. Notably is this the case in the matter of elephantiasis, so common in many of the Pacific islands, where hundreds have obtained relief through operations performed by naval surgeons. I propose in this brief paper to describe two curious affections peculiar to the Asiatic continent and islands, being rarely, if ever, encountered on our own continent or in Europe—and, if so, having an exotic origin—to which will be added some notes on leprosy, the knowledge of which is sufficiently universal not to demand a didactic description. All of these diseases have their origin or persistent existence in local conditions, so that, though we may not clearly determine their etiology the term demographic seems to be applied with distinct propriety. The first of these diseases is the so-called “parangi,” or Spanish pox, which is only known in Ceylon, and has been most carefully studied and reported on by Dr. Kynsey, of the civil service, and came under my observation during a cruise in

the U. S. S. *Juniata* in the year 1883, this description having been embodied in my report of that cruise. The second is psilosis, or sprue, observed on the same cruise in the ports of China.

#### THE PARANGI DISEASE.

The Spanish pox is a disease found in every district of Ceylon, but more especially in the southern districts, where, in 1879, 6,758 cases existed, and throughout the island 10,305. In the vicinity of Colombo it is not often encountered. Parangi seems to have been known from ancient times, but after the introduction of syphilis and other foreign affections characterized by eruption its diagnosis became confused. It bears a striking resemblance to yaws, is not unlike pellagra, and is easily confounded with the syphilitic eruptions, yet it seems to have distinctive diagnostic signs. The etiology of the disease is by no means established, but official inquiry points to insufficient and innutritious food, the absence of meat, the substitution for rice of a poor grain known as kurrakan, filthy habits and surroundings, and the drinking of impure water from nearly exhausted tanks—artificial lakes—where cattle wallow through the day. Microscopic examination has thus far discovered no bacillus or determined any peculiar condition of the blood or secretions. The disease is undoubtedly contagious, and the weight of evidence seems to prove that it is not hereditary or transmitted through natural secretions. All are subject to the disease, but absolute contact of discharges is required, not necessarily an abraded surface, for its propagation. It is only, however, in the debilitated that its worst forms are manifested, and only in those cases does it seem to affect longevity or even the general health. Once cured, a recurrence of the disease is doubtful. Parangi is divided by Dr. Kynsey into three varieties and four stages. The symptoms are thus described by Mr. Garwin, M. B.:

Primarily there is a stage varying from two weeks to three months, during which period an ulcer forms over some bony prominence, generally caused by scratching the part. While this ulcer is healing the second stage declares itself as a slight pyrexia, accompanied by a feeling of debility and general malaise, with articular pains of a dull, shooting character, lasting from two to eight days and terminating in the third stage, that of eruption. The eruption occurs in successive crops, first on the face, then on the trunk and extremities, and not infrequently on the fauces, soft palate, and tongue. It is quite characteristic, though sometimes it becomes confluent in the axilla, nates, and groin, when its distinct features are lost. A papule similar to that of acne first appears, and undergoes various changes which serve to diagnosticate its varieties. In the first and mildest variety of the disease the papule assumes a yellow tinge, loses its prominence, and heals in one direction while extending in the other. In this there is no loss of substance, no discharge, and only a slight desquamation in healing. In the second and third varieties the papule increases to the size of a pea, or larger, becomes very prominent, and its apex roughened from degeneration of epithelium. A gluey matter exudes, forming a crust. The papule shrinks and acquires a brownish-yellow hue, a crack or fissure surrounding its base. It resembles rupia, but the crust is less conical, cockle-shaped and stratified. The third variety is a sequel of this, in those patients who are greatly debilitated, or where the parts have been submitted to friction. Then the exudation is excessive, the papule becomes greatly enlarged, pus forms abundantly and oozes out from beneath the dirty, yellow, soft crust, which is constantly being removed as quickly as it is formed, presenting a condition not unlike that of condylomata. When about to heal the rupial crusts fall off, leaving a clean, granulating surface, appearing like a ripe raspberry, or the crusts may dry up and fall off, exposing a surface already healed. In the condylomatous form healing takes place as in ordinary ulcerations, and in all

cases the resulting cicatrix is invariably deeply pigmented, the natural hue of the skin not being acquired for many months. In rare cases parangi goes on to a fourth stage, which has been attributed to the abuse of mercury. This is characterized by great debility and emaciation, anorexia, extension of the eruption, unhealthy ulceration, with profuse discharge, destruction of the true skin, and excessive deformity, if the patient recovers, through the contraction of cicatrices. When the eruption occurs on the soles of the feet it is termed dumas. In those cases the hard cuticle is distended until it bursts, the pain being excessive, and the eruption appears as a fungous growth, covered with a yellow scab. Early writers on parangi have considered the disease to be a form of syphilis, but this has been completely disproved by the careful consideration lately given to the subject, and the same investigation has proven that it is not a form of leprosy, pellagra, or yaws, but a disease *sui generis*. From syphilis it is distinguished by the absence of the ordinary signs of that affection when it is a disease of inheritance; and where the osseous system is affected in parangi it is always due to the abuse of mercury and does not properly belong to the history of the disease. The character of the eruption sufficiently distinguishes it from lupus; from leprosy it is easily diagnosticated by the absence of the enlarged ear lobes and the characteristic anæsthesia. To framboesia or yaws it bears a striking resemblance, and in the condition known as dumas the same raspberry-like growth is produced. Many still think it to be framboesia modified by climatic influences. The prognosis is always favorable, save in cases which are in the fourth stage. Convalescence is readily established in the first variety, while in the more chronic cases there is little suffering, trifling disturbance of the general health, and ultimate recovery. The treatment is dietetic and medicinal. Under the first head good, nitrogenous food, milk, cod-liver oil, and ferruginous preparations should be ordered in all cases indicating malnutrition. Under the second head the treatment varies with the stage of the disease. In the febrile stage warm baths, diuretics and diaphoretics, saline cathartics, as sulphur and potass. bitart., are ordered. In the eruptive stage mercury is of use, but must be carefully administered, preferably in combination with potass. iodid. Much harm has been done by this drug in the hands of the native vedaralas. For the flying pains the iodide and bromide of potassium in combination are recommended. In this stage arsenic is of use, and the potass. bitart. and sulphur should be continued. Locally, ointment of acid carbolic is applied, and the fungus growth of dumas is destroyed with nitric acid. The warm bath, with soap, should be used daily. The more extensive and intractable ulcerations, lesions of the bones, and abscesses, due to the abuse of mercury in the hands of the native quacks, are best treated by potass. iodid. Locally, stimulating applications are found useful, such as strong tincture of iodine, carbolic acid lotions, turpentine liniment, etc. If the cicatrix is dense it may be separated by an incision, or even excised. Other conditions are treated on general principles. Hospitals have been established throughout the districts where parangi prevails, and every attention is given to the afflicted. The disease, however, must exist so long as there is poverty, defective agriculture, water tanks of insufficient capacity, and general hygienic surroundings of the worst character. As regards inoculation, which is employed to acquire yaws in the West Indies, no reports have as yet been made by the medical officers of Ceylon, though instructed to employ it. In the reports for the year 1871, however, Mr. W. D. Wright makes the following allusion to a custom prevalent in remote parts of the Vanori district. This custom is—

To make children, when they are about 1 year old, partake of rice off a leaf or plate on which a person suffering from the disease has eaten. In a short time pustules appear, resembling itch, on the child's body, and then medicines containing a minute portion of mercury are administered, which cause the pustules to

dry up in seven days, the scales to fall off, leaving deep marks, which, in course of time, disappear. It is said that this is an almost certain prophylactic, and that though the disease may attack one who has been so guarded, the effects are never serious.

#### PSILOSIS, OR SPRUE.

The term "psilosis" is one of recent application to this remarkable disease, but under the name of sprue it has been recognized and observed by all travelers in India, especially in the highlands, in China, its adjacent southern territory, and Java, for a considerable period, being especially studied in the latter island by physicians in the service of the Dutch East India Company, and more recently by those in the Chinese customs, as well as the medical officers of the English diplomatic service, resident in the Chinese ports. In all these countries it has been frequently confused with tropical diarrhoea, muco-enteritis and other forms of intestinal disorder, hepatic irregularity, and stomatitis, but more careful and extended observation has determined it to be a disease *sui generis*, having distinctive diagnostic features and a specific origin, though not traceable to any specially demonstrated microorganism though with our present tendency to interpret the etiology of disease, this is naturally assumed to be the case.

*Definition, etiology, and pathology.*—Psilosis is a disease of tropical or semi-tropical countries, affecting foreigners rather than natives, of insidious approach and chronic remittent continuance, characterized by superficial ulceration of the buccal cavity, tongue, and alimentary canal, salivation, diarrhoea, or irregularity of the bowels, anæmia, and profound debility, disproportionate to the amount and character of the discharges, and atrophy of the muscular and fibrous tissues, which, with the anæmic pallor, gives to the skin a shrunken, aged, deathly appearance—a disease which is at once favorably influenced by change of climate, but, when apparently cured, has a tendency to recur, even in other lands, after the lapse of years, when the patient is exposed to unfavorable climatic and hygienic conditions. As regards cause, we can not as yet go beyond the predisposing condition, which is the want of adaptability of certain constituted foreigners to peculiar climatic surroundings, and the prolonged high temperature of southern Asiatic countries, which, with many observers, is assumed to be the entire pathology of the disease, and, as an exciting cause, accidental, operative, and traumatic conditions, especially those involving the alimentary canal, have been recorded. It is, however, a disease so distinct in its character, that it is more likely to have its origin in some special microbe or parasite which has thus far eluded microscopic investigation. The soft, colorless masses of which the stools are frequently composed are found crowded with bacilli and various forms of cell life, which have been submitted to study, but the special association of any one of these with this disease alone has not been determined. The few necropsies that have been carefully made report an atrophy and ulceration of the mucous membrane of the intestines, but especially the ileum, with a generally normal condition of the liver and pancreas, though the liver is sometimes atrophied, and the pancreas has been found in a state of degeneration, and even with abscess. Beyond these no important changes have been revealed by autopsic observation. The most marked pathological features are the peculiar stomatitis, the salivation, acidity of the stomach and alimentary canal, feeble gastric digestion, with a special acid condition of the contents of the ileum—where the reaction is usually alkaline—and it is here that the coloring matter of the fæces is supposed to be destroyed by bacterial action, or it may be due to the state of hyper-acidity. The stools show some absorption of the fat of milk, which is the most usual form of food in this disease, but most of it is passed from the bowels, the fæcal mass being highly acid. One remarkable effect of the intestinal condition is the effect upon any preparation of iron which may be administered, the metal appearing in fine particles, and the fæces not blackened.

*Clinical description.*—Psilosis, or sprue, appears as a stomatitis, or inflammation of the alimentary canal, and its starting point may be the mouth, stomach, or intestines. The disease has a chronic course, is generally of a remittent character, with periods of almost complete convalescence through a prolonged state of malaise and general debility. The tongue is generally clean, but may be slightly furred, very red, and fissured, the papillæ enlarged and highly sensitive, especially at the tip and edges. The whole buccal mucous surface is swollen and congested, often raw and tender, generally covered with excoriations, perhaps ulcerated, with the gums swollen and bleeding. The salivation is often so profuse as to overflow the lips, creating great discomfort by the constant necessity of swallowing, and deglutition is very difficult and painful, from the condition of the mucous membrane of the mouth being extended into the fauces, œsophagus, and stomach, highly seasoned food and condiments causing absolute agony, while only the blandest food can be ingested. Diarrhœa, with frothy acid evacuations and even choleraic discharges, is usually present, though this may not be the case; but all stools are characterized by being clay-colored or entirely colorless. There is commonly a constant sense of emptiness in the epigastrium. At intervals of several days these symptoms usually abate, when the tongue contracts, the papillæ diminish, its upper surface appearing clean and glazed, as though varnished, the oversecretion of saliva diminishes or ceases, while the diarrhœa is modified, through the condition of the discharge is not greatly changed, and thus a fair convalescence may be established. To this an exacerbation succeeds, and may come on with regularity every two or three weeks, and sometimes at intervals of a few days, the lingual, buccal, and salivary symptoms returning, and now the superficial ulceration recurs or becomes more extensive, with increased difficulty in deglutition and articulation. The disease thus marches rapidly toward the end, with increasing anæmia, the skin appearing ex-sanguine, the conjunctivæ and tongue assuming a yellow pallor. Emaciation also progresses, the muscular being more affected than the adipose tissue, the body becomes withered in appearance, the face is expressive of advanced age, and the debility is extreme. This condition attained, the disease must soon terminate fatally, unless the patient is rescued from his surroundings, his demographic involvement, and transferred to a different clime.

*Diagnosis.*—From thrush it is distinguished by the occurrence of the latter in infantile life, or as an intercurrent condition in wasting diseases of the adult and the grayish-white deposit upon the buccal and pharyngeal mucous membrane, which, under the microscope, displays the easily recognized mycoderma fungus characteristic of thrush, which is a disease responding immediately, in most instances, to proper treatment. The foul tongue and offensive breath (especially marked in the mercurial form) are diagnostic signs of ulcerative stomatitis, and there is usually but slight difficulty in tracing this inflammation to some adequate cause, while in psilosis the tongue is generally clean, fœtor of the breath is not common, and neither bones nor teeth are involved. Lastly, it may be confused with tropical diarrhœa, but the absence of all color from the stools, with the pronounced acidity of the fæces, the ulcerative condition of the mouth and fauces, and the specially marked languor in sprue, with the remittent character of the disease, should be sufficient to determine the diagnosis.

*Treatment.*—Every therapeutic measure has been applied in psilosis, and much relief given by the ordinary remedies addressed to stomatitis and morbid conditions of the organs concerned in digestion, the emollient vegetable oils, such as olive, almond, and cotton-seed oil, being found especially valuable. These, however, have not been curative, but we seem to have in santonin a remedy of great promise, for which we are indebted to George Thin, M. D. He first used it as a vermicide, and discovered that in 5-grain doses, once daily, it has in his practice

controlled the evacuations of psilosis, causing a speedy convalescence, and is apparently curative. Milk, koumiss, rice and other cereals cooked in milk, bouillon without condiments, barley and rice water, flaxseed tea, and similar bland substances must be the form of nourishment, to be given frequently, in small quantities. In a disease so fatal, and one so entirely dependent on the *entourage*, we should, however, remove the patient at once to a radically different climate, where we have the right to expect an immediate change for the better and rapid convalescence.

Of recent writers on this subject the most prominent are C. Begg, M. D., and George Thin, M. D., in the *Lancet* for 1892, who give an interesting and lucid description of this remarkable disease; and in the Medical Report of the Chinese Customs Service for 1880 Patrick Manson, M. D., presents a valuable paper detailing his personal experience with sprue.

#### LEPROSY.

For a long period leprosy, as observed in the Western Hemisphere, was confined to certain widely separated districts of South America, to the West Indies and Mexico, to a small area of the State of Louisiana, and the eastern possessions of Great Britain in North America. But within recent years it has seemed to acquire a new impetus throughout the world. The Chinese nearly sixty years ago brought it to the Hawaiian Islands, the Norwegian colonists have carried it to the great Northwest, and the extension of oriental emigration to the United States has brought with it this dread disease, so that in almost every State and Territory into which the Chinese have penetrated as laborers and servants there are reports of isolated cases which have caused the most intense apprehension lest these should prove centers of infection and leprosy become permanently established in our midst. The facts and the reports of independent observers in all lands where leprosy exists, demonstrating that we are in a period of extension of this disease, calls upon the medical profession in all lands to arouse the people and work with the Governments for its repression. To do this an accurate estimate of our existing knowledge on this subject is of paramount necessity, that we may approach as nearly as possible to a determination of its etiology, mode of extension, prophylaxis, and treatment. The views entertained on this subject by students of the disease have been so widely at variance that for the personal investigation of the leper and the collecting and sifting of evidence, under the important headings above enumerated, a British leprosy commission was organized and sent to India in 1890, which has but recently reported the result of its labors and its conclusions. The commission was composed of members of the colleges of physicians and of surgeons of London, Indian medical officers, and representatives of the "English leprosy fund." A year was spent in the investigation, 2,000 lepers were examined, and answers to carefully prepared interrogatories were received from a majority of the medical officers of the Indian civil service and the medical officers of the army. A wider or a more complete field for a harvest of knowledge can not be conceived, extended by interrogatories addressed to the other colonies and countries similarly affected, and the conclusions of the commission are thus summarized: (1) Leprosy is a disease *sui generis*; it is not a form of syphilis or tuberculosis, but has striking etiological analogies with the latter. (2) Leprosy is not diffused by hereditary transmission, and for this reason, and the established amount of sterility among lepers, the disease has a natural tendency to die out. (3) Though in a scientific classification of diseases leprosy must be regarded as contagious, and also inoculable, yet the extent to which it is propagated by these means is exceedingly small. (4) Leprosy is not directly originated by the use of any particular article of food, nor by any climatic or telluric conditions, nor by insanitary surroundings; neither does it

peculiarly affect any race or caste. (5) Leprosy is indirectly influenced by unsanitary surroundings, such as poverty, bad food, or deficient drainage or ventilation, for these, by causing a predisposition, increase the susceptibility of the individual to the disease. (6) Leprosy in the great majority of cases originates *de novo*; that is, from a sequence or concurrence of causes and conditions, dealt with in the report, and which are related to each other in ways at present imperfectly known.

In 1876 I spent a considerable period at the leper settlement of Molokai, when I made a special study of the disease under the guidance of the lamented Father Damien, who presents the most positive evidence of its contagious character under circumstances of ordinary intercourse, his deathbed confessions to a layman that "he had never known woman" outweighing the calumnious assertions of his enemies that his licentious life was the cause of his becoming a leper. Since that I have seen and studied the disease in almost every land, returning recently to Hawaii to renew my interest in leprosy as manifested in this island Kingdom. And I maintain that here it is to be studied to better advantage than in any other land similarly afflicted, its history as related to the Hawaiian people; its clinical records completely written; the question of cause, heredity, and contagion fully discussed; and segregation, with all therapeutics practiced through a long period of years by local physicians of the highest attainments and foreign physicians of eminence, including the widely celebrated Dr. Arning, of Hamburg, who have given the subject their most earnest application. Therefore the considerations of this British leprosy commission can be responded to more satisfactorily from the position of intelligent experience of those employed in the care of the leper and the strong effort that is being made to eradicate the disease in the islands of Hawaii than in any other portion of the globe where it exists, not excepting India, which was chosen for the special work of this commission. Thus prepared, it is in this manner they respond to the six paragraphs summarizing the report of the commission by six other paragraphs presenting the Hawaiian view of leprosy.

First. It is a disease *sui generis*. It is not a form of syphilis or tuberculosis, these diseases being often coëxistent with leprosy.

Second. It is not diffused by hereditary transmission, though the contrary was long maintained, and there is apparently much evidence to sustain this view; but we have to accept the opinion of Dr. Hansen, of Norway, that, being a disease dependent on the presence of a special bacillus, it can not be classed any longer as hereditary, and further, that if segregation can be properly enforced the sterility of the leper will cause the disease to die out. Segregation, however, is difficult of attainment with such a social people as the natives of Hawaii, against which they are continually arrayed, requiring the strong arm of the law, and even, as recently, the military power to enforce the law in this regard. And when collected at Molokai, the colony is invaded by Kokuas, or friendly attendants, who come and go as they please, while Kamaainas, the holders of Kuleanas, or private estates within the limits of the leper settlement, receive the lepers, and here contact takes place with the outside world, as the Kamaainas can not be disturbed lawfully, and are privileged to go where they please.

Third. It is contagious and inoculable; but Hawaiian experience compels an entire dissent to the statement that "its propagation by these means is exceedingly small," for there is every evidence that it has thus spread over the island. To quote from my own report of 1876, this has been owing mainly to the social habits of the people, viz., large families crowded together in small houses and having the same mats and blankets; the eating of poi with their fingers, all seated around and helping themselves from the same calabash; the drinking of ava in the Hawaiian manner, infused by mastication, and passing the pipe from mouth to mouth, a common Hawaiian custom. To this we may add absolute fearlessness and absence of any disgust for the disease in its worst form and the licentious habits of the race.

Finally, we may add that very rarely do we find a leper who has not acknowledged intercourse with the leprous. To sustain this position there are volumes of evidence.

Fourth. The conclusion, undoubtedly not to be controverted, that leprosy has not its origin in any particular article of food or in any climatic, telluric, or insanitary surroundings, or that it is confined to any race or caste, with the exception that a dry situation with a high temperature is favorable to staying the progress of the disease, is sustained.

Fifth. That leprosy is indirectly influenced by insanitary surroundings, poverty, and bad food is a matter of special observation in Hawaii. Dr. Trousseau states as a cause of the rapid propagation of leprosy so soon after its importation in 1840 the widespread syphilitic and scrofulous cachexia then so common in the Hawaiian race, and since then these have been the victims, as well as the very poor, and those weakened by acute or epidemic diseases, or some shock to the system under these circumstances, as by sea bathing. In all, the disease is latent for many years, it has in other countries been known to so exist for forty years, and these conditions cause its development.

Sixth. That leprosy arises *de novo*, according to the commissioners, has only to be mentioned to arouse a smile of derision, and is a most impotent conclusion to valuable work, which has rather sustained previously expressed opinions of eminent students of this disease rather than added to knowledge of the subject.

As regards prophylaxis, the commission recommended perfect hygiene and segregation, which is all that Hawaiian medical men have found from experience to be worthy of consideration; and with reference to therapeutics the same conclusion has been reached, viz., no cure; that the various oils recommended, especially chaulmoogra oil and arsenic, are palliatives, and all the other proposed remedies have proved utter failures.

My most recent notes on Hawaiian leprosy were made in the years 1890, 1891, and 1892, during which period I visited the leper settlement for the second time. And I will conclude this paper with extracts from a report then made to the bureau of medicine and surgery covering the therapeutic experiments of D. O. Lutz, M. D., of San Paula, Brazil, a former associate of Unna, of Hamburg, and a physician of large experience as a dermatologist, who was commissioned January 12, 1890, as Government physician for the study and treatment of leprosy. After consideration of the matter, he concluded to confine his work principally to Kalihi receiving station, exercising only a general supervision over medical affairs at Molokai, where Dr. Swift was in charge. At Kalihi he was to constitute one of the members of the examining board, that advantage might be had of his diagnostic ability in matters of dermatology, and he was to be permitted to retain 20 lepers for purposes of treatment and experiment. The work of Dr. Lutz really commenced November 26, 1889, and terminated October 12, 1890, when, dissensions having arisen between himself and the board, he was forced to resign. During the continuance of this service at Kalihi he had associated with him, in the care of the lepers and suspects, a competent trained nurse in the person of Sister Rose Gertrude, a young and enthusiastic English girl, whose duty was admirably performed. The period of Dr. Lutz's stay at Kalihi was but eleven months, yet several valuable quarterly reports were made by him to the board of health, and from the first and last I condense the following information: In April, after four months' experience, he speaks encouragingly, and thinks that treatment had suppressed development, especially in tuberculous cases, and, in many, absorption of tubercles, even that of the ear lobes, and disappearance of cutaneous pigmentations, so prominent a feature of the dorsal surfaces, had taken place. Syphilis was found in many cases distinctly separated from the leprous condition and yielding to specific treatment. In several anæsthetic cases, even in very unpromising ones, a partial restitution

of feeling and a diminution of contraction had been noticed, which he credits to treatment. This treatment was chaulmoogra oil and gynocardic acid, its essential constituent, with which he had had previous success in Brazil and Paris. Salol, however, was his chief remedy, first introduced by him in the treatment of leprosy several years ago. It would seem, to judge from Dr. Lutz's observations, that the progress of leprosy was associated with inflammatory conditions and febrile excitement always, and that the salol, acting as an antiphlogistic and febrifuge, stayed the morbid processes. Creosote and guaiacol, its active principle, were given in cases where there was neuralgic pain. Arsenious acid was found not to act favorably, contrary to common experience, and antisyphilitic remedies, especially potassium iodide, were not clearly beneficial in uncomplicated cases. For external use chrysarobin or chrysophanic acid was used and acted favorably in causing the absorption of tubercles and the disappearance of maculo-nervous and psoriasis-like eruptions. It also quickly improved extensive conditions of paræsthesia. Chrysarobin was employed in five-tenths per cent ointments, or in solution with either benzine, chloroform, or similar solvents, always being covered with elastic collodion. Pyrogallie acid was found to act like chrysarobin, but more slowly, and was only employed on the face and hands to avoid toxic symptoms, which are manifested as pernicious anæmia. Ichthyol is praised as combating inflammatory symptoms, and was used both internally and externally.

Dr. Lutz considered infection as furnishing the largest number of patients; heredity, if it really exists at all, as quite secondary, and vaccination as a most doubtful cause in the propagation of the disease; opinions corresponding to those of most dermatologists now engaged in the study of leprosy. In concluding his first report the following important conclusions are presented by Dr. Lutz, after many years of study and experience: Leprosy is a chronic disease and therefore requires a chronic treatment, like syphilis and tuberculosis. While in the latter disease we can not do anything more than help the natural tendency to cure, and all the methods tried in late years have led no further, still the hope survives that specifics may be found, as for syphilis. This latter disease is perfectly curable, although the moment when the cure is accomplished may never be ascertained. But we know that by watching the patient from the first, and curing every fresh outbreak by immediate treatment, we may finally come to a real cure. The stationary tubercles and nerve affections of leprosy do not endanger life, and their removal, which is often possible, does not warrant cure. It is probable that most of the microbes in the tumors are dead, and that the effect of our remedies is only to hasten the reabsorption of the dead material. This may be obtained, perhaps, without a specific action, by an artificial irritation, and hyperæmia. But at the same time we may again throw into the circulation a few surviving organisms and thus promote new outbreaks. We must therefore direct our principal attention to the general treatment. If we learn to recognize the very first outbreak (as I have done during the last years with several patients in my private practice); if we can check it, as seems to be possible, by the use of salol and salicylate of soda; if we treat in the same way every feverish and eruptive period, giving in the intermediate time other remedies which have a favorable influence, and finally slowly remove the morbid deposits where they already exist, we do more to prolong the life of the patient than is done in all the sanatoria for tuberculosis. At the same time we may avoid at least a good deal of the consequences of the untreated cases, and make leprosy, as it has proved with most of my private patients, a rather benignant disease. I believe we shall then see cures which may be attributed, not to extraordinary fortunate chance, but to our methods of treatment.

In his final report, dated October 1, 1890, satisfaction is expressed with the effects of salol, chrysarobin, and pyrogallie acid, and reference is made to cresalol as a

substitute for salol and some experiments with sulfonal. Several patients are referred to as having improved under treatment, and five are mentioned by name as recommended for transfer from the leper to the suspect side of the hospital, presumably because they were considered to be cured of their leprosy. In October, 1890, Dr. Lutz abruptly closed his connection with Kalihi Hospital and terminated his contract with the Board of Health, Dr. Henry McGrew taking his place. On account of the confidence evinced in Dr. Lutz's course of treatment by the natives, all of his therapeutic measures were continued up to the period when the *Charleston* left Honolulu in February, 1891. At this time I was informed by Dr. McGrew that, in his opinion and that of his associates on the board, Dr. Lutz's course of treatment was not curative, and that all patients supposed to have been cured had been committed to Molokai. The Kalihi Hospital, or receiving station, where Dr. Lutz was located, is situated 3 miles from Honolulu, near the seashore and beyond the boundaries of the harbor. Here all suspects are brought, and, after inspection by the board of health, are either declared lepers and sent to the Molokai, detained for observation, or discharged. At Molokai the settlement occupies broad lands, bounded by the sea on one side and a precipitous cliff or pali on the other, and it is inconceivable how exiles could be better cared for physically, medically, morally, and mentally. Comfortable cottages have been built for all; there is a well-appointed hospital, a bountiful supply of provisions and clothing is issued to all, and for the young there are two excellent schools for boys and girls, the Bishop Home for the former and the Damien Home for the latter, both under the control of the Franciscan Sisters. There are two Catholic churches with two resident priests, successors to the lamented Father Damien, and those of other religions receive appropriate ministrations in four special places of worship. Over the settlement a resident governor rules, and a resident physician, Sidney Bourne Swift, M. D., who is a man of superior attainments and close observation, has general medical charge. But the study of the disease and of the bacillus lepræ has thus far been productive of no worthy results. The treatment employed by Dr. Lutz represents the best therapeutics of the day, and yet as good results have been obtained from careful housing, good nourishment, and the treatment of lesions and symptoms according to the principles of good pathology, which will, as previously pointed out, keep the disease in abeyance, and if earnestly pursued prevents it in most cases from shortening life; but the relaxation of vigilance will be followed by rapid and fatal developments. Leprosy in consequence of the opposing influences to the successful operation of the law of segregation maintains its *status* in Hawaii. The biennial report of 1892 shows that there were 1,123 lepers collected at the leper settlement, the previous report giving the number as 1,159.

## MEMORANDA.

(1) Dr. Morwitz says:

If 100 Hawaiians (sexes mixed) had continuous contact with leprosy for a period of years, say five to fifteen, at the expiration of that period no less than 82 would have become lepers, the remaining 18 would be clean, and these latter are the class who are illustrations of leprosy being a noncontagious disease. I have come to the conclusion that about 18 per cent of the Hawaiian race resist the contagion.

(2) Dr. Arning studied the bacillus lepræ for a considerable period in the years 1884 and 1885 at Molokai. He says:

In the so-called anæsthetic cases the bacillus is not found in the anæsthetic patches, in the chronic sores of neurotic parts of the skin, tissue, and bone, but, as nerve excisions have proved to me, in the nerves supplying these mutilated parts with vitality.

Dr. Arning failed in his cultivation of the bacillus in an artificial soil, as did Dr. Lutz, and also in the inoculation of the lower animals, but apparently succeeded with a criminal, Kenau by name, whose sentence of death was commuted

to penal servitude in consideration of his consenting to experimental inoculation with the bacillus. Dr. Arning's experiments established the wonderful vitality of the bacillus lepræ, and its extraordinary power of resisting putrefaction, an examination of the dead showing the germs to be in a state of activity after three months of interment. This observation may be of great importance in an inquiry into the etiology of leprosy. As regards the case of Kenau, he was inoculated September 30, 1884, and in March, 1885, microscopic examination revealed the bacillus in large numbers near the spot of inoculation, and again fourteen months afterwards, though there were no evidences of leprosy. Later, and after Dr. Arning's departure, Kenau became a developed leper and subsequently died of the disease. This case promised to be one of great importance as establishing the contagion or inoculability of leprosy, but investigation, made subsequent to Dr. Arning's departure, seems to prove that Kenau came from a leper family and by heredity, if that is admitted as a factor, or like exposure to cause, if we wish to exclude contagion—may have been affected with the disease. No such experiment, however, was necessary to an unprejudiced observer of Hawaiian leprosy to prove the truth of contagion.

---

DOES THE PRESENCE OF LEPROSY IN THE UNITED STATES,  
CANADA, AND MEXICO CALL FOR THE SUPERVISION OF THEIR  
SEVERAL FEDERAL GOVERNMENTS?

By BENJAMIN LEE, A. M., M. D., Ph. D., of Philadelphia, Pa.,

*Secretary of the State Board of Health of Pennsylvania.*

At the meeting of the American Public Health Association, which took place in the city of Brooklyn in the year 1889, I had the honor to present a paper in which attention was called to the constantly increasing opportunities for the introduction of leprosy into the United States from outside, through our seaboard ports, and the consequent expediency of making that disease the subject of maritime quarantine or exclusion. A resolution was then adopted calling the attention of the United States Government to the subject and suggesting that definite action be taken to prevent the further introduction of the disease. The recommendation received immediate attention from the national authorities and a regulation was adopted by the Treasury Department ordering that any person affected with leprosy discovered attempting to enter the United States at any port of entry should be returned to the country whence he or she came. Under this regulation a number of lepers have thus been denied entrance to the country. So easy is concealment of the disease, however, in its earlier stages, so insidious is its approach, and so numerous are the avenues through which it may gain an entrance from the British possessions on the north, from the West Indies on the southeast, and from Mexico and Central America on the south, quite independently of our seacoast quarantines, that we may reasonably look for a very considerable augmentation of the number of persons suffering from this infection already within our borders. I therefore venture to solicit the attention of the section for a few moments to the question of the domestic quarantine or segregation of lepers. In order to obtain data of a somewhat reliable character on which to arrive at a conclusion, circular letters have been addressed to the various State and provincial boards of health and to physicians especially engaged in the study and treatment of skin disease containing certain inquiries. The replies to that addressed to official bodies, taken in connection with the published observations of well-known specialists, indicates that within comparatively recent times, since 1858, for instance, between five and six hundred lepers have had official recognition in

this country and Canada, and that at the present time 117 cases of the disease are known to the authorities. It also appears that there is an entire absence of uniformity in the methods of dealing with these unfortunates, and that in the majority of the States they are entirely ignored. As Mexico had not at the time that I began this investigation taken part in the deliberations of the American Public Health Association, I unfortunately have no original data from that Government. This is the more to be regretted, inasmuch as they would undoubtedly prove of great intrinsic interest, and also as the rapidly increasing intercourse between the two nations makes the question one of practical importance. The disease is well known, however, in the western regions of that country. There are usually about thirty under treatment in hospital in the City of Mexico, separate wards being assigned them, but segregation is not insisted on. This much for cases of which official cognizance has been taken and most of which have been treated and maintained by governments, whether national, State, county, or municipal. There remain to be considered those which have been under the care of private practitioners. Believing that all such cases would have been seen, in consultation at least, by those who had made diseases of the skin a specialty, and feeling also that the opinions of such men were entitled to especial consideration in regard to the mode of propagation of this affection, and to the necessity, if any, for the adoption of measures for its restriction, I addressed the following series of interrogatories to 34 prominent dermatologists, representing all sections of the country from Canada to California:

DEAR DOCTOR: Believing from the nature of your specialty that you must have met with cases of leprosy, and desiring to obtain reliable data as to its occurrence in this country, I make bold to request the favor of a reply to the following interrogatories: 1. How many cases of that disease have you met with in the course of your practice? 2. How many cases have you at present under treatment? 3. What have been the ages, sexes, and nationalities of your cases? 4. Does your experience lead you to think that there are concealed cases in your city? 5. What, in your opinion, would be the best means of caring for lepers in this country: (a) The establishment of a national leper colony, (b) the establishment of State or city leper houses, or (c) the assignment of special wards in general hospitals to lepers? 6. What are, briefly, your views as to the mode of propagation of the disease, and the expediency of isolation of those infected with it? An answer to the above inquiries, which, if you so desire, will be considered confidential, will be sincerely appreciated by

Yours, very truly,

BENJAMIN LEE.

Twenty-one replies have been received, the results of which may be summed up as follows: Number of cases treated, 90; of which 7 are stated to have been in hospital. Number at present under treatment, 3. In some instances the respondents decline to state. This is only what was to have been expected and can excite no surprise. The ages of the patients have ranged from 9 years to 70. Of 76 cases in which the sex was reported 67 were males and 9 females. Of 32 cases in which the nationality was given 10 were natives of the United States, 6 were Chinese, 12 were South American or West Indian, 2 were Swedes, 1 was Irish, and 1 Canadian. Eight of those reporting consider it probable that there are concealed or unrecognized cases in the large cities in which they themselves reside. Of course the larger the city the greater the opportunity for hiding and therefore the greater the probability of this course being pursued. The case which recently occurred in my own city, in which a leper in the ulcerous stage was discovered employed as cook in a hotel and had been kept carefully out of sight by the proprietor, is fresh in everyone's mind. Nearly all of the cases which the authorities of our large towns have had to take care of have been lurking in secret places, fully aware of the nature of their affliction. As to the best means of caring for lepers—the three suggestions of the circular having been, as will be recalled, the

establishment of a national leper colony, the establishment of State or city leper houses, or the assignment of special wards in general hospitals; fourteen replies were in favor of the assumption of the care of these unfortunates by the National Government in a leper colony or colonies, on the score of humanity to the victim and of benefit to science as well as of protection to the public. The suggestion was made by one that in every large city a ward in a general hospital should be set apart for the observation of suspects before they were removed to the central colony or hospital. Two were of the opinion that the several States or cities should establish leper houses. Ten were convinced that the treatment of lepers in special wards of a general hospital or at their own homes even, under proper environment and police surveillance, would not be attended with risk to the public, but five of these considered that, all things taken into account, the General Government was the proper authority to assume this burden, and that better results would thus be obtained than in any other way. As to the mode of propagation no doubt was expressed by any of the twenty-one as to the communicability of the disease. Nine took strong ground as to its conveyance by inoculation alone, either mediate or immediate, considering its manner of communication almost identical with that of syphilis, while nine others were not inclined so to restrict it, preferring to say that the precise mode of infection was to them unknown. Only two referred to heredity as a possibility. It is quite safe to say that this latter doctrine is now entirely without scientific adherents among those who have enjoyed a large field of observation. Now, I am quite willing to admit that there is overlapping in these reports; that some cases which have been seen in consultation by two physicians have been reported by both; also that many of the cases reported by physicians are included among those reported by boards of health. From this exception, however, we may exclude almost entirely the cases officially reported from New Brunswick, British Columbia, California, Louisiana, Wisconsin, Minnesota, and Iowa. Making all due allowances for duplication, it must be allowed that whether we consider the extent of geographical distribution, the differing nationalities, the various ages, or simply the number of victims of this most horrible of all diseases, the general resultant is such as to render the question worthy the attention of the national legislatures of all the countries represented in this congress.

### THE COMMUNICABILITY OF LEPROSY.

By Dr. BEAVEN RAKE,

*Medical Superintendent of the Trinidad (British West Indies) Lepers' Asylum, Late Member of the Indian Leprosy Commission.*

A brief statement of my views regarding leprosy may be divided under six headings, as follows:

1. *Bacteriological evidence.*—It is now admitted that leprosy is associated with the presence of a specific bacillus. This ought to be found at some period or other in the course of the disease. If this bacillus is not found it is due either to imperfect examination or to the fact that in some old and long established cases of leprosy the bacillus may die and disappear from the tissues. Numerous attempts have been made to cultivate this bacillus by Hansen, Neisser, Bordosi, Uffreduzzi, Giantuico, Campana, Arning, and the members of the Indian Leprosy Commission, but in no instance has success been certain. Uffreduzzi's culture was accepted by Baumgarten, but neither his culture nor that of any of the others produces leprosy when injected into animals. Thus only the first of Koch's four postulates as to the dependence of a disease on a specific microorganism has been fulfilled in the case of leprosy, and though from analogy with other diseases we are

driven to the conclusion that the disease is due to a bacillus we are still without proof of the assumption.

2. *Inoculations of animals.*—Many different kinds of animals have been inoculated with leprous products by Neisser, Damsch, Vossius, Köbuer, Hansen, Campana, Thia, Kansic, Arning, Leloir, Bordoni, Uffreduzzi, and many other observers in various parts of the world, but hitherto without success. Neisser described a local growth in a dog, but there was no general development of leprous tubercles. I have made experimental inoculations of animals in the Trinidad Leper Asylum, extending over about nine years, but the results have been negative. Some of the animals have been under observation upward of four years, one as long as eight years from the date of inoculation to that of death, and no development of leprosy has taken place. I have also fed fowls and pigs with leprous material for periods of one or two years and the results in these animals have been equally negative. Melchen and Ortman have described dissemination of nodules in the viscera of rabbits after inoculations of leprous tubercle. But Wesener and Hüppe believe these nodules to be those of tuberculosis, though Arning and Ruffer accept them as leprous. On the whole we must regard the evidence derived from inoculations of animals as negative, and this seems to support Beriner's view that leprosy is an essentially human disease and can not be transmitted to animals.

3. *Inoculations in the human subject.*—Arning inoculated Kenau, a convict in the Sandwich Islands, with leprosy, and the man developed leprosy three years afterwards. But leprosy is extremely prevalent in these islands, and Kenau may have derived it from other sources. It was also discovered later that three of his relatives were lepers, so that it would seem that in his family there was a peculiar aptitude for taking the disease. If a criminal in a country such as England where leprosy is not endemic could be inoculated with the disease, and if such criminal after inoculation developed leprosy, we should have a scientific proof of the inoculability of leprosy. Profeta, in Italy, inoculated himself and several healthy individuals with leprosy, but none of them developed the disease. A physician in Norway performed a similar experiment on himself and several other healthy people, but here again the evidence was negative. Holst and Iitsch also failed to inoculate healthy individuals. Hansen inoculated anæsthetic lepers with material from tuberculated leprosy, but without success. I have inoculated 40 anæsthetic lepers in the Trinidad Asylum with material from tuberculated lepers, 2 of the 40 have developed tubercles, but this evidence is not of absolute value, for anæsthetic lepers have been described by Leloir as occasionally becoming tuberculated. Thus the evidence obtained from inoculations in the human subject may be regarded as negative with the exception of Arning's case, and this is open to grave doubt.

4. *Vaccination.*—Hardner, in 1887, reported a case in a tropical island where a child became leprous after being vaccinated with lymph from another child who afterwards developed the disease. Danbler, at the Cape of Good Hope, also recorded 2 cases in which he believed that leprosy was conveyed by vaccination. More recently Chew, in Calcutta, has brought forward a number of cases in which he believes that leprosy was invaccinated. But all these cases occurred in districts where leprosy was endemic, and are, therefore, open to the objection brought forward in the case of the convict, Kenau, viz., that the disease may have been derived from other sources. If a child in a country free from leprosy were inoculated with lymph from a country where leprosy is prevalent and after such vaccination developed leprosy we might consider that the proposition had been scientifically proved. An experiment which somewhat approaches the above hypothetical one has been performed in India, where during a period of some twenty years Surg. Maj. Pringle was in the habit of bringing vaccine lymph down from the hill districts of British Garhwal, a locality in which the percentage of leprosy

is very high, and vaccinating children in the plains between the Ganges and Jumna, where leprosy is far less common. Census returns taken at intervals of ten years in these districts showed not only a decrease of leprosy in British Garhwal, but also in the vaccinated districts in the plains. If vaccine lymph were an efficient mode of conveying leprosy we should have expected an increase of the disease in the plains. Arning and Simpson have described leprosy bacilli in the vaccine lymph of lepers, but examinations of nearly 40 specimens in the Trinidad Asylum and of nearly 100 by the leprosy commission in India were negative. We may therefore conclude that in no case has it been proved that the leprosy has been conveyed by vaccination.

5. *Practical experience.*—By this I mean histories of contagion given to us by patients, or cases reported by others. While in India we examined some 2,000 lepers, and many histories of contagion were given, but on close examination all these broke down with the exception of one case, that of an attendant at the Leper Asylum at Calicut, who contracted the disease after he had been for some years at the asylum. Father Damien's case is often quoted as an example of contagion, but this, like the Calicut case just mentioned, and like all cases reported from leprosy-infested countries, is open to the objection that the disease may have been derived from other outside sources. To eliminate this fallacy of concomitant variations we must look to cases of contagion in countries free from leprosy. Two such cases seem free from doubt. One was reported by Dr. Hawley Benson in Dublin. A man returned from service in India and developed leprosy. His brother, who had never been out of the United Kingdom, slept in the same bed with him, and about two years afterwards this brother also became a leper. The cases were shown at the Dublin Medical Society, and there seems to have been no doubt as to the diagnosis, for doctors were present who had seen leprosy abroad. The second case occurred in Maryland, and was reported by Dr. Atkinson. A woman who had not been out of the country became leprous some years after contact with a leper. In Maryland we know that leprosy is not endemic. Thus we may, perhaps, admit two positive cases against a very large number of negative ones, for it must be remembered that there are hundreds of doctors, nurses, and attendants in constant contact with lepers, but these never develop the disease.

6. *Alleged increase of leprosy.*—It has been said that leprosy has largely increased of late years. Published figures show this statement to be incorrect in most parts of the world where annual leper censuses are taken. In Norway there has been an almost uninterrupted downward curve for the last thirty years, in spite of the fact that in that country segregation has never been absolute. Until 1885 there was no law compelling the isolation of lepers, and even then it only enacted that they should be separated from the rest of the family to the satisfaction of the sanitary inspector. Failing this they were to go to an asylum. Dr. Ransia, of Molde, states that only 14 have come into the asylum since 1885 by reason of the new law. In Iceland, also, there has been an enormous decrease in the last hundred years. There has been no segregation. In India the censuses of 1881 and 1891 showed an absolute decrease of over 4,000 lepers, and this in spite of the fact that in Burmah, Rajpootana, Travancore, and the central province states no leper census was taken in 1881, while in 1891 a full census was taken, showing many thousands suffering from the disease. It is therefore almost certain that the decrease in India is much greater than that shown in the official census return. In India hardly any attempt is made to isolate lepers. In the Northwestern States of North America about 160 Norwegian lepers came over many years ago. Only about 13 lepers now remain. There has been no development of the disease in their descendants nor in any Norwegian or others in contact with them in this country; segregation is not strictly carried out among them. In Trinidad the ratio of lepers to the population has remained almost stationary; there is no

compulsory isolation. In the Sandwich Islands segregation is compulsory, but in spite of this the official returns show that in the last twenty years the number of diseased has almost quadrupled. In Meniel, on the Russian border, there has been a small increase of leprosy in late years; no contact has been traced with lepers. It would thus appear that in Norway, Iceland, India, and the Northwestern States of North America there has been a large absolute decrease of leprosy apart from the segregation; that in Trinidad the ratio of lepers to the general population has remained practically stationary, while in the Sandwich Islands, where compulsory segregation has been enforced for many years, there has been an enormous increase. It seems that in certain districts the disease may increase by reason of certain local factors of which we are ignorant, as, for example, in Meniel.

*Conclusion.*—We believe that leprosy is due to a specific bacillus, and therefore we must admit the possibility of its communicability. Evidence, however, derived from the sources mentioned above shows that if it is communicable at all it is in such rare instances and with such difficulty that for practical purposes we may disregard the possibility. I would place leprosy and tuberculosis in one class. I believe that the bacilli of both are present in the dust of certain localities and that dwellers in such localities are constantly coming in contact with the bacilli. Only in those who are weakened from various causes do the bacilli find suitable soil for development, and these individuals become the subject of leprosy, or tuberculosis. The accumulated evidence goes to show that leprosy is rather less communicable than tuberculosis, and that if we isolate lepers, we ought *a fortiori* to shut up those suffering from tuberculosis.

#### SUGGESTIONS FOR A PLAN TO ENABLE THE MASTERS OF MERCHANT VESSELS TO PROPERLY CARE FOR THOSE ATTACKED AT SEA WITH YELLOW FEVER.

By G. FARRAR PATTON, M. D., of New Orleans, La.

It is a fact well established by the experience of quarantine physicians whose duties have brought them into contact with vessels upon which yellow fever has appeared while at sea that of those attacked with the disease a great many die from the obvious want of proper care and treatment. From a careful comparison of statistics it would appear that the mortality from yellow fever on shipboard ranges from 50 to 70 per cent, against a death rate of from 15 to 30 per cent in the great epidemics that have visited our American cities in this century. This is easily explained by taking into consideration the want of experience, and consequent excusable ignorance, of the average shipmaster as regards the management of yellow-fever cases. Unfortunately our science, far reaching as it is, does not as yet enable us to offer to the unacclimated any reliable measure of protection in the face of exposure to this disease. Certain measures have been brought to the notice of the public as tending to guarantee immunity against the special infection of yellow fever; but without reviewing these in detail, it is safe to say that the medical profession and the public alike refuse to put any faith in them. It would seem that the only safeguard against yellow fever is the avoidance of exposure. If non-intercourse with infected places could be maintained, the spread of the dreaded pestilence would cease, but as long as the requirements of commerce call for the sacrifice the hardy seaman will continue to risk his own life and endanger the safety of healthy communities by traffic with the fever-infected ports of the Tropics. We know that by a rigid system of quarantine we can protect ourselves, but we are practically powerless to protect these wanderers of the

sea against the insidious and deadly infection to which the exercise of their calling exposes them. We are bound, however, as members of a great and humane profession, to consider the question of extending to them, when they may be stricken with pestilence upon the lonely seas, such aid and guidance as may be possible. Therefore, while we are assembled in council to devise and perfect schemes for the protection of our homes and families against imported pestilence, shall we not also give some thought to these unfortunates whose fate it is thus to suffer hardship, privation, and disease, far from the reach of medical aid or other human help, save that of rough though kindly shipmates? These considerations have forced themselves upon the attention of the writer during a long experience with quarantine work, dating back to 1877, and an almost daily observation of the habits and needs of seafaring people since that time. It is with the firm conviction that something can be done, and easily done, in the way of enabling the masters of merchant vessels to supply rational and fairly successful treatment to such of their people as may develop yellow fever at sea, that the plan here proposed for indorsement by the Pan-American Medical Congress is presented. It frequently happens that no cases of fever occur among the crew of a vessel until after sailing from an infected port. It would almost seem as if breathing the fresh air of the open sea develops the latent poison in the patient's system. The captain, congratulating himself upon getting away from Havana or Rio de Janeiro without losing any of his men, soon finds himself in command of a floating hospital as case after case of fever develops among his crew; and with no knowledge or experience as to the care and treatment of the sick, he is confronted with the grave responsibility of attending them. Now, while the treatment of yellow fever, as regards the mere giving of medicine, is comparatively simple, there is perhaps no disease in which an early diagnosis, with reference to expectant treatment and the enforcement of absolute rest in a horizontal position, is of greater importance. In fact, it may be said that upon this enforced repose, especially during the fatally delusive "stage of calm," and upon the withholding of unsuitable articles of diet, the patient's life hangs as upon a thread. Among men so little accustomed to illness as sailors these vitally important conditions are difficult to secure. The writer calls to mind an instance in which, the cook of a vessel being ill, the steward, also ill but feeling better, arose on the fourth day of his fever and crawled to the galley to cook dinner, only to faint from weakness and die within twenty-four hours. On the same vessel the first victim, a sturdy seaman, refused to yield to the attack, and stood his watch of four hours at the wheel, from which, when relieved, he had to be carried to the fore-castle. The captain of that vessel was by no means a hard master to his men, but he simply did not know what to do. It might easily happen that a panic would spread among the crew of a ship, the timid imagining themselves sick, while others, really ill, but actuated by a stern devotion to duty, would sacrifice their lives by continuing at work. To guard against this, and in view of the known disposition of mates to suspect alleged sick men of malingering, it is important that the master of every merchant vessel should possess a clinical thermometer and be familiar with its use, a requirement so simple that no man capable of navigating a ship need hesitate about complying with it. Since circumstances force the ship-master, in addition to his other duties, to assume the grave responsibility of superintending the care of his men when attacked with yellow fever at sea, those who have it in their power to supply him with information that will better fit him for the task should come to his aid; and this is what is contemplated in the plan here proposed. This plan, briefly stated, is as follows: Let it be made part of the duty of consuls in yellow-fever ports to furnish the master of every vessel clearing from such ports with a printed memorandum of instructions, to be issued by competent medical authority under Government supervision, and setting forth in

simple language the principal points which it may be deemed necessary to impress upon the shipmaster for his future guidance. Among these points the one demanding the first consideration is perhaps that of placing the vessel in the best possible sanitary condition by thoroughly cleaning and disinfecting, after approved methods, every article of clothing, bedding, etc., on board, fumigating rooms and cabins, washing out and disinfecting bilges, and in every way striving to destroy any germs of disease that may be present. The crew should be officially notified that as they value their lives they must report promptly the first symptoms of illness. In this connection the instructions should describe the method of using the thermometer as being the only reliable guide in discovering at the very outset the existence of fever, thus furnishing an invaluable means of detecting malingerers. In the opinion of the writer an expectant plan of treatment should be pursued in every case, however mild the symptoms. The details of this treatment need not be enumerated here; but over and above all other directions that of forcing the patient, after the disease is established, to remain absolutely at rest in a horizontal position should be rigidly insisted upon. With hardy men like sailors it often requires the exercise of positive authority to compel obedience in this particular, especially where attention to the wants of nature is concerned. Due stress must be laid upon the delusive feeling of comfort experienced during the so-called "state of calm," for it is here that the greatest vigilance is required to prevent the patient from exerting himself in some way that will prove fatal. Seafaring people are hearty eaters, and it is often difficult to prevent the patient on shipboard from taking unsuitable food under the mistaken impression that he needs something substantial to sustain his strength. This point deserves especial emphasis, and no schedule of instructions would be complete that did not give explicit directions as to the proper nourishment of yellow-fever patients, as well as the rules for the administration of stimulants. The consul charged with delivering the instructions should require every captain not already provided with a thermometer and the several articles of diet enumerated in the printed list to supply the deficiency before sailing. To secure faithful nursing, which in yellow fever is recognized as being the most important requirement, two intelligent and trusty men should be detailed as attendants upon the sick, and it should be impressed upon them that, in the opinion of a majority of experts, the patient himself does not diffuse the poison which causes the disease, but that it may be retained by his clothing. Therefore, if all the clothing and bedding has been previously disinfected and the rooms fumigated, the attendants need feel no special apprehension beyond that of the possibility of their already having the germs of the disease in their own systems. If these various points be forced upon the attention of an intelligent shipmaster just prior to sailing, his crew will certainly have a far better chance of being successfully treated should yellow fever appear among them than is at present the case. From a long and intimate association with seafaring people the writer is firmly convinced that the majority of shipmasters will not only receive such instructions gladly, but, as a rule, they can be depended upon for the faithful execution of every detail. In 1880, while on duty at the quarantine station below New Orleans, the author of this paper published one of similar purport in two of the great English newspapers in the hope that the leading maritime nation of the world might be induced to take the initiative in such a measure. However, beyond some gratifying editorial comments, one of which appeared in the London Lancet, no special notice seems to have been taken of the matter. Now that the opportunity presents itself to put forth another appeal, under the auspices of a great international congress such as this, it is earnestly hoped that a more effectual impression may be produced.

## THE QUARANTINE LAW OF JAMAICA.

By JAMES CECIL PHILLIPPO, M. D., of Kingston, Jamaica, British West Indies.

Whereas it is desirable to consolidate and amend the laws relating to quarantine:

*Be it enacted by the governor and legislative council of Jamaica, as follows:*

1. The quarantine law, 1869 (law 37 of 1869), and the laws amending the same (law 32 of 1872 and law 10 of 1892), shall be, and the same are hereby, repealed: *Provided*, That notwithstanding such repeal any penalties incurred under the said laws, or either of them, prior to such repeal may be recovered and enforced as if this law had not been passed.

2. In this law the term "infected place" means any port or place or country or definite portion of a country, as hereinafter provided, where yellow fever, the plague, cholera, or any epidemic disease of a contagious or infectious character, in fact prevails, or which the governor in privy council may declare to be an infected port or place. An infectious or contagious disease shall be deemed to "prevail" in a place, within the meaning of this law, when such disease has been communicated to one person, or more than one person, through the medium of a person sick of such disease arriving in such place, or of goods, personal effects, or other things, introduced into such place; but it shall not be said to prevail in a place merely because a single case, or a small number of cases of disease as aforesaid, has been imported into such place, where the disease has not been communicated to others. The word "vessel" means any ship, vessel, or boat; and the word "master" means the master, officer, or other person for the time being in charge or command of such vessel, and the term "visiting officer" means a person appointed at any port of the island by the governor for the purpose of carrying out the provisions of this law. "Lazaretto" shall mean any vessel moored in any quarantine ground, or any place on shore contiguous to a quarantine ground, appointed by the governor in privy council under the provisions of this law, within which any person arriving on any vessel that shall be put into quarantine may stay during the continuance of such vessel in quarantine, or if such vessel leaves the island instead of going into and remaining in quarantine, during such period as such vessel would have had to continue in quarantine if she had not so left the island.

3. The governor is hereby authorized to appoint not less than three, or more than five, persons to be a board, to be called "the quarantine board," to hold their offices during pleasure, and from time to time to fill up the vacancies in such board; and also, in case any member of the board appointed as aforesaid shall be temporarily absent from the island, or be ill or otherwise unable to act, to appoint some person to act as a member of the board during the absence or inability to act of such member. Such board, of whom two shall be a quorum, shall have full power and authority to superintend and enforce the carrying out of the laws, rules, and regulations, for the time being in force relating to quarantine: *Provided*, That the board heretofore appointed under the provisions of law 37 of 1869 shall be deemed to be the board appointed under the provisions of this law, without further or other appointment.

4. The governor is hereby authorized from time to time to appoint such officers as may appear to him to be necessary to carry out, under the direction of the said board, this law, and the rules and regulations made thereunder, and all such officers shall hold their offices during pleasure.

5. It shall be lawful for the governor in privy council from time to time to make such rules and regulations as to him shall seem fit for the more effectual carrying out the provisions of this law and to secure the due performance of

quarantine ; and for the government of all vessels, persons, animals, and cargo put into quarantine under the provisions of this law ; and for prescribing, in each port of the island, a point beyond which no vessel shall come, and from which no person shall land, or cargo or luggage shall be discharged, until such vessel shall have been visited by the visiting officer ; and for prescribing, subject to any exceptions mentioned in such rules, a distance from vessels in quarantine within which it shall be unlawful for any person to come, and within which it shall be unlawful to send or permit to be sent any person or thing ; and also, from time to time, to make rules and regulations respecting the disinfection of vessels and their contents liable, under any of the provisions of this law, to be disinfected before such vessels shall be allowed to discharge cargo. Such rules and regulations may extend not only to the mode of disinfection to be adopted and the extent of such disinfection and the sum of money to be paid by the master of the vessel as the cost of the same, but they may also prescribe any port or ports to which all vessels arriving in this island, having goods, merchandise, animals, passengers, or passengers' luggage on board, liable as aforesaid to be disinfected, shall repair for the purpose of being disinfected before landing any of such goods, merchandise, animals, or luggage. The governor in privy council may, from time to time, alter or amend any such rules and regulations ; such rules and regulations, and altered or amended rules and regulations, shall be published in the Jamaica Gazette, and, after such publication, shall have the same force and effect as if the same had been herein particularly specified.

6. Whenever the governor in privy council shall have reason to believe that any disease of a contagious or infectious character prevails at any port or place, or in any country, or definite portion of a country, or that it is probable that any such disease may be brought into the island from any port or place, or country or portion of a country as aforesaid, it shall be lawful for him to declare, by notification in the Jamaica Gazette, that such port, place, or country is an infected place : *Provided*, That when the governor in privy council shall, under the provisions of this law, declare any port or place to be infected, he shall specify the disease or diseases with which such port or place is infected. It shall be lawful for the governor in privy council, by a notification as aforesaid, to withdraw, and to declare to be no longer in force, any such public notification as aforesaid.

7. Every vessel arriving at any of the ports of this island shall, immediately on arrival, and before having any communication with the shore, or passing the point prescribed under rules or regulations made in that behalf, be visited by the visiting officer of the port to which such vessel shall come, who is hereby authorized and required, at a convenient distance from such vessel, to put the following questions, or such of them as may be necessary, and any other questions which he may consider desirable : (1) What is the name of the vessel, and of the master ? (2) To what port or place does she belong ? (3) From whence do you come ? (4) To what port or place are you bound ? (5) At what ports or places have you touched in the course of the voyage ? (6) What vessels have you had any intercourse or communication with during your voyage, and from whence did they come ? (7) Have you any and what bill of health ? Produce it. (8) Did you carry any bill of health with you to the port or place where you took in the cargo or passengers you now have on board ? From what place ? Were the said bills of health clean, unclean, or suspected ? (9) Did any contagious or infectious disease prevail in any degree at the port or place from which you sailed, or at any of the ports or places at which you touched ? If yes, say what disease prevailed, and at which port or place. (10) What number of officers, crew, passengers, or other persons have you on board ? (11) Were any of these taken on board at any port or place during the voyage to this island ; if yes, who were so taken on board, and at what port or place, and on what day or days ? (12) Are any persons on

board your ship suffering under any contagious or infectious disease ; or have any persons died or been ill of any disease of that nature in your passage to this island ; and, if any, what number ? (13) If any have died or been ill of any such disease, have their bedding and clothes been destroyed ? (14) In the course of your voyage have any persons on board suffered from sickness of any kind ? What was the nature of the sickness and when did it prevail ? How many persons were affected by it ? (15) How had the persons attacked been employed before they came on board ; had they been employed in loading or unloading the vessel ? (16) Did the persons who were ill fall sick nearly about the same time, or within a few days of each other ; or did the disorder spread successively from one to another and increase considerably ? (17) What is the number of persons now ill on board your vessel ? Are the convalescents able to be on deck ? If so, parade them on the gangway. (18) Have there been any deaths on board during the voyage ; if yes, what were the causes of the deaths, and when did such deaths take place ? (19) Have you any person on board who has left (name of infected port or place) within fourteen days ? (20) Where did you take in the cargo now on board, and when ? If at more than one place, state the places. (21) Was any cargo, or were any letters, parcels, or articles of any kind put on board at (name of infected port or place) ? If yes, state what was put on board, and when, and whether any special precaution was taken with respect to such thing.

8. The said visiting officer may, if he thinks it necessary, go on board any such vessel and examine the master, officers, crew, and passengers thereof respectively, as to their state of health then and during the voyage, and may examine the journal or log and ship's papers of such vessel, and put any of the questions set forth in the preceding section, or any other question which he shall think desirable.

9. Any master or other person who shall conceal from any visiting officer the true state of the health of the crew or other persons on board such vessel, or who shall give an untrue answer to any inquiry made by such visiting officer under the authority of this law, shall be liable to a penalty not less than £5 and not exceeding £100.

10. No master or other person belonging to or on board of such vessel, and no pilot or pilot's assistant who shall have proceeded on board such vessel, shall quit the same, for the purpose of landing or communicating with the shore, before such vessel shall have been visited by the visiting officer, unless permission to do so be granted in writing by the visiting officer.

11. No person, the pilot or his assistant excepted, shall proceed on board such vessel before she shall have been visited by the visiting officer, unless permission to do so be granted to him in writing by the visiting officer.

12. Any person offending against the provisions of either of the two last preceding sections shall be liable to a penalty of not less than £5 and not exceeding £50.

13. The quarantine board shall, with the approval of the governor, appoint suitable places for quarantine grounds, and shall have power, with the like approval, from time to time to change such places.

14. If any vessel shall have arrived from or touched at any infected place, or shall have on board any person who has come from such place, or on board which any person may have died during the passage to this island, or may be ill of any contagious or infectious disease, or shall arrive without a clean bill of health from her port of departure, or if the visiting officer shall have good grounds to suspect that such vessel has arrived from or touched at any such place as aforesaid, or has on board any such person as aforesaid, or that any person has died or is ill as aforesaid, the said visiting officer is required to put the said vessel into quarantine.

15. Notwithstanding that any vessel arriving at any port of the island shall not be liable, under any of the foregoing provisions of this law, to be put into quarantine, it shall be lawful for the visiting officer at the port of arrival, in case any

such vessel shall have on board any goods or merchandise that the visiting officer shall have reason to believe are in direct transit from an infected place, so as to make such ship and her cargo a possible source of infection, in his discretion to put such vessel into quarantine for the purpose of there undergoing a process of disinfection: *Provided*, That it shall be the duty of any visiting officer exercising the powers vested in him by this section to at once report the cases to the quarantine board, who may in their discretion support or overrule his decision; save as aforesaid, such discretion shall be absolute, and shall not be subject to be questioned in any court of law: *Provided*, That when any vessel arriving at any port of this island, not being liable under any other provisions of this law to be put into quarantine, shall be put into quarantine under the provisions of this section for the purpose of her being disinfected, such order shall not prevent the landing of any passengers arriving by such vessel, together with such of their luggage as has not been in the hold of such vessel, provided that such passengers leave such vessel with such of their luggage as aforesaid within twelve hours after her arrival, and before such vessel has anchored in the quarantine ground. After the expiration, however, of the above period, or the anchoring of such vessel as aforesaid, all the provisions of this law applicable to vessels put into quarantine shall apply to such vessel, and every person and thing on board her, until the disinfection of such vessel and goods and cargo shall have been completed. Goods or merchandise shall be deemed to be in "direct transit" from an infected place when such place shall have been the place from which their transmission to this island commenced, notwithstanding the fact that in the course of such transmission they may have passed through places not infected, or that the port or place at which they have been put on board the ship bringing them to this island shall not be infected.

16. When the visiting officer shall have allowed any vessel arriving at the port of which he is visiting officer to communicate with the shore without being put into quarantine, and within fourteen days of the arrival of such vessel at such port any person on board such vessel shall fall sick of any contagious or infectious disease, or any fact or circumstance is brought to the knowledge of the visiting officer which, had the same been brought to his knowledge on the arrival of the vessel, would have led him to put such vessel into quarantine, it shall be lawful for such officer, and it shall be his duty, to put such vessel into quarantine. Thereupon the master, officers, and crew of such vessel shall accompany the same to the quarantine ground: *Provided*, That if, before such vessel shall have been put into quarantine as aforesaid, the master, officers, or crew, or any of them, shall have landed and shall be ill on shore, and his medical attendant shall certify that it would be dangerous to his life to send him back to the said vessel, it shall be lawful for the visiting officer to excuse such person from accompanying the said vessel: *Provided also*, That it shall be the duty of the said visiting officer to report to the local board of health of the port any action taken by him under this or the preceding section.

17. Subject to any provisions of this law to the contrary, when any vessel has been put into quarantine by the visiting officer of any port under the provisions of this law, the following rules shall apply, that is to say: (1) Such vessel shall, between sunrise and sunset, hoist a yellow flag on the top of the mainmast, and keep the same there displayed, and shall, during the night, keep displayed such light as may be prescribed by rules made under this law. (2) Subject to the proviso hereinafter contained, she shall, with all persons, animals, goods, merchandise, and other things on board her at the time of her being put into quarantine, proceed to, and anchor at and remain in, the quarantine ground appointed for such port, until duly released from quarantine under the provisions of this law. (3) Until such release as aforesaid, no person on board of or belonging to

such vessel, or any part of the cargo, stores or lading of the same, or any article or thing belonging to the passengers, master, officers, or crew thereof shall be permitted to leave, or be removed or taken from such vessel, either to go or be put on shore (except at a lazaretto as hereinafter provided), or on board of any other vessel in any port of this island, unless by the direction of the governor in privy council, or of the quarantine board, or of some person duly authorized by him or it, and every such vessel, and all goods, persons, and merchandise thereon, and all vessels and persons having communication with the same, shall be subject to such rules and regulations as may be made by the Governor in privy council. (4) Until such release as aforesaid, no person except the visiting officer, or such other person as may be authorized by the quarantine board, shall go on board such vessel; and no article or thing shall be taken or received on board such vessel, except by the direction of the quarantine board, or of the said visiting officer. (5) Notwithstanding that any vessel, with all persons on board her, shall be entitled to be released from quarantine, no passenger on board such vessel shall be entitled to land in this island until he shall have given to the visiting officer an account of his intended movements in the island, so as, in the opinion of the visiting officer, to enable the several district medical officers of the island and the police to report to the governor if any infectious or contagious disease has shown itself among any of them: *Provided*, That nothing herein contained shall make it unlawful for any vessel, ordered into quarantine under the provisions of this law, to put to sea and again enter the same or any other port of the island, instead of going into quarantine: *Provided*, That any such vessel proceeding to sea as aforesaid shall, while at sea, be deemed to be in quarantine to all intents and purposes, and subject to all the rules applicable to a vessel in quarantine until, on again entering the same or entering any other port of the island, she shall be released from quarantine by the visiting officer of such port.

18. No vessel arriving at any harbor of the island, having on board any ballast composed wholly or in part of earth, sand, or mud, as defined by section 2 of law 36 of 1873, shall be allowed, so long as she has any such ballast on board, and for such period as may in the judgment of the visiting officer be necessary, after discharge of the same, for the purification of the vessel, and retaining her under observation, to enter such harbor; but the visiting officer shall, so long as such vessel has any such ballast on board and for such period as aforesaid, treat such vessel in all respects as he would treat her if she had on board a person ill of some contagious or infectious disease: *Provided*, That in any harbor where the place set apart for the deposit of ballast, under the provisions of section 26 of law 36 of 1873, is within the limits of such harbor, if such place is certified by the quarantine board to be a place where such ballast as aforesaid may be thrown without prejudice to the public health, it shall be lawful for the said visiting officer, under such conditions as he shall see fit, to allow such vessel to proceed to the place aforesaid, although such place may be within the limits of the harbor: *Provided*, That, while proceeding to such place, and while lying there, such vessel shall be deemed to be in quarantine to all intents and purposes, save as to the obligation to anchor at the quarantine ground; after the discharge of such ballast as aforesaid, such vessel shall return to the quarantine ground, and there undergo such purification and be under observation for such period as the visiting officer may consider necessary.

19. All vessels put into quarantine shall, together with all goods, merchandise, animals, and passengers, and passengers' luggage thereon, be disinfected before being released from quarantine.

20. It shall be lawful for the governor in privy council from time to time, by order published in the Jamaica Gazette, absolutely to prohibit the importation from an infected place of such articles or things (to be named in such order) as

the governor in privy council may consider to be specially calculated to carry infection, when the same are the produce of an infected place, or have been, in the course of their direct transit to this island within the meaning of this law from the place of production, on board any vessel having on board a person ill of any contagious or infectious disease. Such article or thing shall thereupon be deemed to be a prohibited article or thing within the meaning of section 37 of the customs consolidation law, 1887, and all the provisions of the said law shall apply to the same accordingly.

21. Subject to any special rules and regulations of the governor in privy council, and to the proviso hereinafter contained, the following rules as to the duration of quarantine shall be observed: (1) All vessels on board of which any person shall be sick, or shall have been sick, of any contagious or infectious disease, or shall have died of such disease within fourteen days before her arrival at this island, shall remain in quarantine until the expiration of fourteen days from the day when such sickness shall cease, or shall have ceased, or from the day when such death occurred. (2) All vessels that shall have sailed from or touched at any infected place, or shall have any person on board who shall have come from any such place, shall remain in quarantine for such time, not exceeding fourteen days, as shall be directed by the quarantine board on a due investigation of all the circumstances of the case. (3) If, during the continuance of a vessel in quarantine, any person on board such vessel falls sick of any contagious or infectious disease, such vessel shall be liable to remain in quarantine for a further period of fourteen days from the day when such sickness shall cease: *Provided*, That no vessel shall, under the provisions of this law, be liable to be put into quarantine by reason only of her coming from an infected place, or of her having on board any person who has come from an infected place, unless such vessel or person shall have been in such place within the times herein limited; that is to say: (a) In case such infected place is infected with cholera, six days; (b) with yellow fever, ten days, or (c) with smallpox, fourteen days previously to her arrival in this island. In case any place shall be or be declared to be infected by reason of the prevalence therein of some infectious or contagious disease other than those above named, it shall be lawful for the governor in privy council to fix the period before arrival in this island which must have elapsed to entitle any ship to the benefit of this proviso.

22. Any master of a vessel ordered into quarantine who shall not, forthwith after receiving such order, cause such vessel to proceed to the quarantine ground, shall be liable to a penalty not less than £100 and not exceeding £400; and it shall be lawful for the visiting officer, or any person called to his assistance, to enforce the removal of any such vessel to the quarantine ground, and to use all necessary means for that purpose.

23. The master of any vessel put into quarantine who shall omit during the day to hoist and keep flying a yellow flag as required by this law, or, during the night, to hoist and keep alight a signal lantern, shall be liable to a penalty not less than £5 and not exceeding £50: *Provided*, That any such flag or signal lantern shall, on demand, be furnished by the quarantine board.

24. Any person offending against the provisions of subsections 3 or 4 of section 17 of this law shall be liable to a penalty not less than £5 and not exceeding £50.

25. If, during the time that any vessel is in quarantine, the master thereof shall, without the permission of the quarantine board or of the visiting officer, quit, or knowingly suffer any passenger, seaman, or other person on board to quit, such vessel, or any goods, articles, or things whatsoever, to be taken from such vessel, he shall be liable to a penalty not less than £10 and not exceeding £100.

26. Any person who, during the continuance of quarantine, leaves the vessel without proper permission in that behalf, may, in addition to the penalty herein-

before mentioned, be apprehended by any constable or other person, and compelled to return to the said vessel, or be taken before a justice, who may order that such person be returned to the said vessel, or be confined in some lazaretto or other suitable place of confinement, for such period, not less than two days nor exceeding fourteen, as he may think fit.

27. Any person who shall go on board a vessel in the performance of quarantine without permission as aforesaid may be compelled to remain on board the said vessel, and be subject to the rules and regulations thereof, during the continuance of the quarantine, or until such time as to the quarantine board shall seem fit.

28. The governor in privy council is hereby authorized, whenever it shall be thought necessary, to provide, at the public expense, one or more vessel or vessels moored within any quarantine ground, or any buildings on shore contiguous to any quarantine ground, as a lazaretto for the purposes of this law, and to cause the same to be fitted up as a lazaretto for such use and purposes as the quarantine board shall, with the approval of the governor, from time to time order and direct.

29. The governor in privy council is authorized from time to time to frame such rules and regulations as may be deemed expedient for the government and direction of any such lazaretto, and of such persons as may belong thereto or be placed therein, and to alter or amend such rules. And it shall be lawful for the governor in and by such rules to require that, before any person shall be allowed to enter any such lazaretto, such sum as shall be fixed by such rules for the maintenance of each person while in such lazaretto shall be prepaid, or secured to the satisfaction of the visiting officer.

30. Any person, except the visiting officer, who enters or leaves any lazaretto without permission from the quarantine board, or from the said visiting officer, may be dealt with in the manner hereinbefore provided in the case of a person without permission going on board or leaving the vessel when put into quarantine, and shall be liable to the like penalties.

31. Any officer or person appointed to enforce the performance of quarantine who shall desert from duty, or shall infringe, or knowingly suffer or permit any person to infringe, the provisions of this law, or of any rules and regulations in force concerning quarantine, shall be liable to a penalty of not less than £5 and not exceeding £50, and shall be subject to immediate dismissal.

32. Any person who shall knowingly conceal, or clandestinely convey, any letters, goods, wares, or merchandise from any vessel liable to or in the performance of quarantine, or from any vessel, house, or other place where any persons or goods shall be subjected to quarantine, shall be liable to a penalty of not less than £10 and not exceeding £50.

33. As soon as any quarantine shall have been fully performed by any vessel or person, the visiting officer or other person appointed by the governor in that behalf shall grant a certificate to that effect; whereupon every such vessel, or person, and all cargo and goods on board such vessel, shall be liberated from all detention on the ground of quarantine.

34. It shall be lawful for the governor in privy council to enforce any rule or regulation to be made in pursuance of this law by a fine or penalty not exceeding, in any one case, the sum of £10.

35. All penalties incurred under this law, or the rules and regulations to be made in pursuance thereof, may be recovered before any two justices, who, in default of payment, are hereby authorized to commit the offender to the nearest jail for any period not exceeding six months: *Provided always*, That upon payment by the offender of the penalties and costs, after commitment, his imprisonment shall cease.

36. All penalties which shall be recovered and paid under this law, or the rules and regulations aforesaid, shall be paid to Her Majesty, her heirs and successors, for the public use of this island.

37. Any visiting officer or other officer appointed to carry out the provisions of the quarantine law, and any person who shall have preferred any charge against any person of an offense under this law, shall, if such charge be dismissed, be deemed to be a "party aggrieved" by such judgment of dismissal within the meaning of the appeal regulation act, 1857.

38. For the protection of persons acting in the execution of this law, all actions and prosecutions against any person for anything done in pursuance of this law shall be commenced within three calendar months after the act committed, and not otherwise; and notice in writing of such action, and the cause thereof, shall be given to the defendant one calendar month at least before the commencement of the action, and in any such action the defendant may plead the general issue, and give this law and the special matter in evidence at any trial to be had thereupon; and no plaintiff shall recover in any such action, if sufficient amends shall have been tendered or paid into court by or on behalf of the defendant; and if a verdict shall pass for the defendant, or the plaintiff shall become nonsuit, or discontinue any such action after issue joined, or if, upon demurrer or otherwise, judgment shall be given against the plaintiff, the defendant shall recover his full costs as between attorney and client, and shall have the like remedy for the same as any defendant hath by law in other cases; and although a verdict shall be given for the plaintiff in any such action, such plaintiff shall not have costs against the defendant unless the judge before whom the trial shall be shall certify his approbation of the action and verdict obtained thereon.

39. It shall be lawful for the governor to authorize, by warrant upon the treasurer, payment of any expenses incidental to the execution of this law.

40. Nothing in this law contained shall extend, or be construed to extend, to prevent the delivery, by the officers in charge of Her Majesty's mails, of any mails that may from time to time be on board of any steam vessel, under such rules and regulations for the prevention of the introduction of any of the before-mentioned diseases as may from time to time be made by the governor in privy council, who is hereby empowered to make such rules and regulations with regard to the landing and receipt of the said mails, and in regard to the coaling of the said steamers in any port within this island.

41. It shall be lawful for the governor in privy council from time to time to suspend the operation of this law, or any part thereof, and for such period of time as may be thought expedient, and again to revive the same, or any part thereof.

42. All rules and regulations existing and in force in relation to quarantine at the time of the passing of this law, so far as such rules and regulations are not inconsistent with, and might have been made under, the provisions of this law, shall be and remain in force until other rules and regulations shall be made under this law.

THE DISTRIBUTION OF DISEASE BY ISTHMIAN PRACTICES; OR THE DIRECT RESPONSIBILITY OF COLOMBIA, SOUTH AMERICA, ON ACCOUNT OF THE INTERMENT AND DISINTERMENT OF THE DEAD ON THE ISTHMUS OF PANAMA.

By WOLFRED NELSON, M. D., of New York City.

The title of my paper may excite some surprise, but that which follows, I believe, will justify it; and if this contribution shall lead to an investigation and verification of my statements my efforts will not have been made in vain. When I reached Panama, in May, 1880, during an epidemic of yellow fever, the burial of the masses in the Campo Santo and the regular disinterment of them were practices sanctioned by forty years of uncriticised freedom. Apart from the old-time *bovedas* (of which more anon), the small Campo Santo, or "God's acre," was on the left of the road leading to the Boca del Rio Grande. For fully forty years previous to the time referred to the masses, after death, were buried in that small enclosure. It was less than an English acre in extent; nearer three-quarters of an acre, I should say. Year after year the same ground was dug over and over again to make way for new tenants. Coffins were seldom used. A coffin at Panama is deemed a positive luxury by the masses. In the few instances where coffins were used they were turned out when the ground they occupied was needed, together with their contents, under a fierce tropical sun. The practice then was, and is now, to rent a coffin, called by the French, in happy phrase, *cerceuil d'occasion*. The coffin was carried by friends to the Campo Santo. There the body was taken out and lowered into the grave, wrapped in its winding sheet. The coffin, having earned *dos soles*, or \$2, was taken back to the undertaker's in the city of Panama, to spread new disease. The soil of that cemetery had my close attention. It was largely argillaceous, or clayey, mixed with sand, a soil the absorbent power of which is of the lowest. To repeat, for fully forty years a highly remunerative business had been done in burying and disinterring bodies there. Having, with the late Mr. John Stiven, of Panama, faced an epidemic of smallpox and yellow fever, I joined him in denouncing the practice in the *Star and Herald*, of Panama, in English, and in *La Estrella de Panama*, in Spanish, each of us making a plain statement of the facts over our respective signatures. The articles created a profound sensation. The president of what was then the sovereign State of Panama, it has since been deprived of its sovereignty, and to-day is a federal department ruled from the national capital, or *Santa Fé de Bogota*, was Don Damaso Cervera. He promised the board of health of the State, from which I had resigned, in common with Drs. Iturraldi and Nouel, that the practice of disinterring the dead should stop. In the meantime the very large mortality incident to the work on the Panama Canal, directed by the leading *undertaker* of the century, Count Ferdinand de Lesseps, had made necessary the opening of a new cemetery. This new burial place was within 150 feet of a narrow glen or valley in which were two old-time Spanish wells, dug down for 50 or 60 feet below the level of the five cemeteries there, called, respectively, the "Campo Santo," the "New Cemetery," the "Jewish Cemetery," the "Foreign Cemetery," and the "Chinese Cemetery," situated beyond the new one. Incredible as it may seem, water, literally cemetery drainage, was taken from these two wells and sold by *aquadores* in the city of Panama for drinking purposes. In our published articles we denounced the wells. The president promised that the selling of the water taken from them should cease. For a time the disinterment of the dead was discontinued, since there was ample room in the new cemetery, but the water from the wells was sold as formerly. The old-time cemetery, after four decades of fertilization by thousands of bodies, became green with grass, and forgotten, as far as the lay mind was concerned. Soon the new ceme-

tery, in spite of its great size, was wholly filled; row after row of graves, each marked by a plain cross bearing a number and a date. The concessionaire, Don Nicanor Obarrio then and now—he owned the wells and had a money-making undertaking establishment near by them—began burying bodies in a large field just back of a line of new bovedas in the new cemetery, these bovedas being a line of vaults or niches running parallel with the main road, or that already referred to as leading to the Boca. The construction of the bovedas I shall refer to later. Midway in the section of bovedas was an opening in the masonry and a gateway leading to the field in question. Therein the energetic and enterprising Señor Don Nicanor Obarrio placed the new cemetery's overflow. But here pray pardon a glance backward. Adjoining the Campo Santo was a vast quadrangle in stone, the old-time bovedas. It had an entrance on the main road, and one directly opposite leading into a field lying toward the Bay of Panama. Within that stone enclosure were four sides of a square, all in masonry, or three tiers of openings, each large enough to admit the coffin of an adult. When the coffin had been placed within, the aperture externally was closed by brickwork and cement, or by a slab of marble, on which was the usual inscription, "*To Fulano de Tal*" or "*To Doña Anita*," as the case might be. Rent for these burial niches had to be paid in advance for eighteen months. At the end of that time if new rent was not forthcoming a Colombian eviction was in order. The coffin and its contents were taken out of the gate leading to the field, and there dumped. Occasionally, when the pile became too large, it was burned. The bovedas system is used by the best classes of the Isthmus. In the Foreign Cemetery, the fifth in that locality, bodies are buried in the earth, there to stay. In some instances, in the case of bodies laid away in the niches of the bovedas, the rent required was renewed, and a very few of the dead in that quadrangle were left in peace. But eviction was the rule. The majority, like their poorer brethren over the way, were transients. So much for the bovedas system as it is operated at Panama to this present day and hour. To return briefly to the new cemetery: It was opened in July, 1884. The ground was consecrated with impressive formalities. A military guard and a band of the Zapadores were present, as were also prominent Government officials and members of the consular corps. It was a half holiday in the city. The affair took on an air of festivity that I had hitherto failed to observe in cemeteries; the joyousness of a graveyard had failed to impress me in the past. Between July, 1884, and the 12th of April, 1886, that new cemetery had received for burial in the earth 3,884 bodies, quite apart from the hundreds buried in the bovedas or niches. Not only had the cemetery been filled, but work was going on in the field in the rear. As a faithful historian, I may say, *inter alia*, that the opening of the annex was unattended by any ceremonial. Panama was making a new record for herself as a pestilential center.

Mr. President and members of this section, this is not the "tale of a traveler." What I have described continues to this very day and hour. I have official authority for my statement. I have made reference to the crosses over the graves, the first of which was numbered "1," with the date and "1884." The crosses bore no names. A ledger gave the name of tenant No. 1. Pray note the paper cross that I hold in my hand. Its center bears the number "2,558;" above is the date "1886;" below, the date "1887;" to the left is the date "1889," and to the right, the date "1891." What may that mean? Simply that the number of the grave is 2,558, a permanent distinction; in addition, that said grave had four successive tenants from 1886 to 1891. In other words, that the new and large cemetery was dug over four times in five years. In conclusion, I can but add in the words of a distinguished American, a statesman admired at home and respected abroad, that the state of things in Panama "is a condition and not a theory." It remains now for this body of Pan-American sanitarians and scientists to say what the world is going to do about it.

## RESPONSIBILITY IN SPREADING DISEASES AND DEATH.

By Dr. WOLFRED NELSON, of New York City.

An individual is amenable to the laws of the country to which he owes allegiance. When he violates the law of a country other than that of his birth or adoption the laws of that country deal with him. Common sense is common law, and common sense, we are told, is genius in working attire. Nations are mere collections of individuals; they have a responsibility to neighboring nations and to the great family of nations. When a nation is a peace disturber or a law-breaker, international law is called into play to correct mischievous tendencies and prevent undue aggressiveness. Under Anglo-American auspices arbitration offers a remedy equal to all emergencies; a peaceful and friendly way of adjusting all differences, be they what they may. As health laws take or should take precedence, let us as sanitarians try and apply some of the foregoing reasoning to the important themes to be here discussed.

The Isthmus of Panama has been rightly called the "gate to the Pacific." It is a narrow strip of land, a trifle under 40 miles in width, and by rail  $47\frac{1}{10}$  miles. It unites Central and South America, its location being at the extreme northern end of South America. That strip connects two mighty oceans, and the Panama Railroad is the link that binds Colon on the Atlantic to Panama on the Pacific. For rough purposes of geographical comparison, place before your mental vision an hourglass in a horizontal position. Let the bulb to the right represent South America, the constriction or neck in the middle the Isthmus of Panama, and the bulb to the left Central America. So much for a crude idea of the three Americas from a geographical standpoint, two of them being vast continents whose littorals are washed by two oceans. Steamer lines converge at Panama and Colon, landing and receiving passengers and cargo. Those making Colon hail from ports in France, Spain, England, Germany, the West Indies, and the United States. Several of the lines named have a coast service for Central and South America. Their cargoes and passengers cross the Isthmus of Panama, there to take any of the lines making the Gulf and the Bay of Panama. They run south from Panama for South American ports; north from Panama for Central American, Mexican, and Californian ports. At San Francisco they connect with transpacific steamers. All of these return to Panama with passengers and cargo for Atlantic and transatlantic ports. The Isthmus of Panama is one of the world's highways, a veritable gate to two oceans.

The water-borne diseases in the Tropics, with which a number of us are most familiar, are yellow fever and smallpox. Many close students of yellow fever deem it a disease of seaports, pure and simple. Of course where introduced during hot weather, under favorable conditions, epidemics result. The sunny South is indebted for its epidemics to the West Indies and Spanish main. I make this statement boldly. Some of us who have studied and traced epidemics both of smallpox and yellow fever within the Tropics will recall ships as their carriers. So much for yellow fever and smallpox. Cholera is the third of the water-borne diseases. The last epidemic was traced to a vessel from Ireland which landed her passengers at New York City. From New York the disease was carried to Panama. At the time the late President Grant was a captain in the United States Army and on the Isthmus with troops en route to California. Steamers from Panama for California left the disease in every port of Central America and Mexico at which they called, and from the coast it extended inland and upland, making fearful havoc. In view of my statements in a paper on the "Burial and Unburial of the Dead on the Isthmus of Panama," and the consequent liberation of millions of germs of yellow fever and smallpox, one must recognize the pernicious results

of such practices and Colombia's responsibility in spreading disease. She is a disease producing and distributing Republic. I beg to emphasize my views as a former practitioner at Panama by quoting Dr. Quijano Wallis. He was vice-president of the Panama board of health and a Colombian. In an official communication he said, in reply to an inquiry made by the board of health of the State of Louisiana:

Comuníquenos que el estado sanitario actual en los puertos de Panama y Colon es por lo general bueno, pues no existe al presente epidemia reinante ninguna, siendo como es conocido que la viruela, la fiebre amarilla y las fiebres palustres, en sus infinitas variedades y formas, nunca faltan en estas regiones intertropicales en donde son verdaderamente endémicas.

I communicate that the actual sanitary condition of the ports of Panama and Colon is in general good, as at present no epidemic disease reigns, it being well known that smallpox, yellow fever, and the paludal fevers, in their infinite varieties and forms, never are absent in these intertropical regions, where they are truly endemic.

Yellow fever is yellow fever. I have seen it at Panama, Mexico (west coast), Cuba, and in Tampa, Fla. The disinterring of the dead of yellow fever is not allowed in the British West Indian Islands. To my mind (and I make the statement as a student of the disease) Isthmian practices are directly responsible for an endless supply of yellow-fever germs. As we know, they always find a soil in newcomers. They die and the germs are committed to the earth, to be unburied *de novo*, and again are sent on their death-dealing mission. The heat, soil, and moisture of the Isthmus are ample to keep up an uninterrupted supply.

Dr. Domingo Freire, the distinguished Brazilian physician, has made prophylactic vaccinations or inoculations against yellow fever a success. As far back as 1882 he discovered in the earth of the cemetery at Sta. Isabel, in Brazil, a specific germ in the soil over the graves of yellow-fever victims. All who are familiar with that classic, "The Formation of Vegetable Mold through the Action of Worms," by the late Dr. Charles Darwin, know full well the agency of worms in bringing disease germs to the surface. Many of the germs are almost indestructible. Students of yellow fever are aware that it reached the Isthmus of Panama from the West Indies. From the Isthmus it spread up and down the coast of Central and South America and Mexico, in which it is endemic. Pray recall Dr. Quijano Wallis' official statement regarding Colombia. From the endemic centers epidemics have their origin and are further spread by steam carriers. Both coasts of Central and South America and Mexico have been swept by them. I include Costa Rica, Nicaragua, and Guatemala.

I have referred to water-borne diseases. To-day we know only too well that cholera is spread largely by water carrying the bacillus. Here pray permit me to state that during the five months that I spent in Santiago de Cuba, the oldest city in the West Indies, Dr. Urbano Guimera was conducting extensive researches, making cultures of the yellow-fever germ, etc. He found that sea water made an excellent culture fluid. In Havana I had the pleasure of examining the cultures of Drs. Carlos Findlay and Delgado. At Panama I was familiar with the excellent work done by Dr. Girerd. I am a firm believer in the protection afforded by yellow-fever inoculation; a statement made by me to Surg. Gen. Wyman in this city five years ago. My faith now as then remains unshaken. Dr. Domingo Freire has been and is a public benefactor. The unburial of the dead is not peculiar to Panama. It seems to be a Spanish-American and Spanish West Indian custom. In Santiago de Cuba the dead are taken from the bovedas. While there I photographed a number of metallic coffins that had been evicted with their contents. The quadrangle or bovedas of the city of Leon, in Nicaragua, is a large, wide and deep, well-like structure. In it were bones from evicted coffins. Such practices are vastly perilous to the human family and the world, and in the interest of humanity and common decency should end. In Cuba yellow fever is a permanent

quantity. Year by year, for nearly one hundred years, it has been deadly in Havana. It is domiciled all over that beautiful island. There are parts of Havana where the atmosphere reeks day and night with the faecal odor. Cuba is a source of constant danger to the South. In the future, as in the past, that fair, fertile land will suffer from yellow fever. She will pay for trading with West Indian ports, where disease is generated, buried, and unburied, and liberated broadcast. The several diseases referred to are preventable diseases. Their prevalence is a blot on our scientific attainments and a disgrace to *fin de siècle* civilization.

What measures will shut out smallpox, cholera, and yellow fever? I take the liberty of answering my own question by replying, "An ideal quarantine station, or the Holt system as it exists below New Orleans on the Lower Mississippi." Therein is an effective remedy. The creation of Dr. Joseph Holt, of New Orleans, is a quarantine with whose actual workings I am familiar. It stands and ever will be a monument to the skill and clear foresight of an American sanitarian, whose name and fame are world-wide. The same system obtains at Galveston, Tex. I likewise paid it a special visit. The press of this great country has expressed much solicitude for Canada, fearing that cholera may reach the United States by that channel. As a Canadian, I may state that an ideal quarantine exists on Grosse Isle in the Gulf of St. Lawrence. Dr. Montizambert is in charge of it. It, with the Holt system, can not be improved upon. Canada will look to herself. All that care and science have indicated has been done.

While I have attempted to set forth the responsibility of Spanish America and Cuba in propagating disease, I have not forgotten cholera. For it and its pestilential centers the Far East should be called to the bar of nations. I have stated the case from my standpoint. Let us hope that measures will be devised by this Pan-American Congress to blot out these preventable diseases. Energetic action of an international character failing, the future will be but a repetition of the past and the present—disease and death!

### PESTILENTIAL CONDITIONS.

By A. N. BELL, A. M., M. D.

Modern sanitation, as undertaken in England fifty-five years ago, was based upon the recognition of the relation of local conditions to the death rate of the people; and the coincidence of its practice and the progressive reduction of the death rate ever since is the unanswerable argument for the establishment of sanitary methods everywhere. Indeed, the scientific investigation of preventive medicine essentially depends upon the registration of the causes of death. The year 1838 was the first complete registration of births, marriages, and deaths, including the registration of the diseases which were the causes of death, in England. It was the beginning of the sanitary movement in that country. Hitherto it had been the almost universal practice there, as elsewhere, when and wherever a pestilential disease broke out in a community to attribute it to a foreign source. During the most devastating epidemic of which we have any reliable history that ever prevailed—that which swept through Europe and northern Asia about the middle of the fourteenth century—the people were content and even encouraged to live without regard to personal cleanliness; to dwell in unventilated houses, on swampy ground bestrewn with putrescible material of all kinds; and to consume tainted food and drink foul water, while the communities severally berated one another and instituted quarantines for protection from pestilences which they all alike cultivated. "Plague" had been universally identified with Egypt up to that period, as it was for several centuries thereafter; and, though not always of the

same type, it was scarcely less common in England and in several European countries than it was in Egypt. The descriptions of the pestilential condition of London, by Erasmus, early in the sixteenth century, and of Cairo, by Volney, nearly two centuries later, are here incorporated as illustrative examples of conditions whose record should never be lost, and which may well be held up as object lessons to some communities in the present generation. Erasmus, of Holland, during a temporary residence in London, wrote to Dr. Francis, the physician of Cardinal Wolsey, minister to Henry VIII, as follows:

I often wonder, and not without concern, whence it comes to pass that England for so many years hath been continually afflicted with pestilence, and, above all, with the sweating sickness, which seems in a manner peculiar to the country. We read of a city which was delivered of a plague of long continuance by altering the buildings according to the advice of a certain philosopher. I am much mistaken if England, by the same method, might not find a cure. First of all, they are totally regardless concerning the aspect of their doors and windows to the east, north, etc.; then they build their chambers so as not to admit a thorough air, which yet, in Galen's opinion, is very necessary. They glaze a great part of the sides with small panes, designed to admit the light and exclude the wind, but these windows are full of chinks, through which enters a percolated air, which, stagnating in the room, is more noxious than the wind. As to the floors, they are usually made of clay, covered with rushes that grew in fens, which are so slightly removed now and then that the lower part remains sometimes for twenty years together, and in it a collection of spittle, vomit, urine of dogs and men, beer, scraps of fish, and other filthiness not to be named. Hence, upon change of weather a vapor is exhaled very pernicious, in my opinion, to the human body. Add to this that England is not only surrounded by the sea, but in many parts is fenny and intersected with streams of brackish water, and that salt fish is the common and favorite food of the poor. I am persuaded that the island would be far more healthy if the use of these rushes were quite laid aside and the chambers so built as to let in the air on two or three sides with such glass windows as might be either thrown quite open, or kept quite shut, without small crevices to let in the wind; for as it is useful sometimes to admit a free air, so it is sometimes to exclude it. The common people laugh at a man who complains that he is affected by the changeable and cloudy weather; but for my part, for these thirty years past, if I ever entered into a room which had been uninhabited for some months, immediately I grew feverish. It would also be of great benefit if the lower people could be persuaded to eat less of their salt fish, and if public officers were appointed to see that the streets were kept free from mud, and that not only in the city, but in the suburbs. You will smile, perhaps, and think that my time lies upon my hands, since I employ it in such speculations, but I have great affection for a country which received me so hospitably for a considerable time, and I shall be glad to end the remainder of my days in it if it be possible. Though I know you to be far better skilled in these things than I pretend to be, yet I could not forbear from giving you my thoughts, that, if we are both of a mind, you may propose the project to men in authority, since even princes have not thought such regulations to be beneath their inspection.<sup>1</sup>

Though England was at that period among the most advanced of civilized nations, the admonition was of no, or at most of but little, avail. Some nominal "sewers" were constructed, but with a prohibition of all connection with them by house drains, or drains from water-closets or cesspools, under severe penalties. Concessions were provided for, however, as special privileges, so that if a man wished to take measures for the protection of the health of himself and family, he could do so only under special favor. Moreover, every builder built according to his own fancy, and houses continued to be "run up" without the slightest regard to drainage or decency, and under the restriction of a tax on light. That pestilential diseases continued under such conditions, and even until nearly two centuries later, to rival those of the Middle Ages in other centers of population, is perfectly consistent with the abundance of such material as they are now known to depend upon. The description of the conditions of plague by Volney, as witnessed by him at Cairo in 1783, more than a century subsequent to the great plague of London, is good for

---

<sup>1</sup> Malcolm's London, p. 459

all time. The people were crowded in close, small, damp dens, thick with the odors of their own impurities and those of the heated marshes. Their food was scanty and unwholesome, cooked over fires with dried manure for fuel. Ignorance, despotism, and poverty combined to make them in every respect a degraded people; but one good custom obtained, which the practice of better conditioned Oriental nations had communicated to them; this was the burial of their dead outside their towns. It was thus that, when the pestilence raged, he was able to count the removal of 1,500 corpses daily out of Cairo. The attack was accompanied by a famine, from a deficient inundation of the Nile, and the European was shocked as he passed through the streets by the dead lying here and there; and the living, who had scarcely life enough to be distinguished from the dead, imploring the passer-by for relief.<sup>1</sup> The conditions of cholera in India at the present time, and as they seem to have been maintained from our first practical knowledge of them—gained by the commercial relations of that country with other countries which were and still are found to maintain approximate conditions—rival the conditions of the sweating sickness in London and of the plague in Cairo. According to the official reports of Dr. M. C. Furnell, sanitary commissioner at Madras:

In all India there died during 1879 5,000,000 people, of whom fever killed 3,500,000; cholera killed off 265,000. In some years it is much worse than this. A good deal of this mortality is preventable, and the use of impure water is, I feel persuaded, answerable for much of it. When the cholera was making its way down from the northwest to our presidency at the end of 1881 and the commencement of 1882, I was asked by an energetic collector to send him a few simple rules on sanitation of villages, that he might publish them in his district Gazette. Subsequently I found myself inspecting a municipality in the north, and the manager showed me a resolution calling attention to my circular, and resolving that two important tanks, which I will call tanks A and B, should be strictly set aside for drinking purposes, and a policeman set over each to prevent people washing their bodies and clothes therein. I confess I felt very pleased and proud when I read this; I felt that we were getting on. Next morning I was going round the town, when the manager pointed out in the distance a tank, which he said was the bund of tank A, one of the tanks in which washing of clothes and bodies was strictly prohibited. "Oh," I said, "let us go and look at it." We went. The doctor of the station and the manager of the municipality were with me. We were soon there, and it was certainly a magnificent tank. There were crowds of people at all four sides, and all or nearly all busily engaged washing their clothes, and those that were not doing that were bathing their bodies! The expression on the face of my friend, the manager, when he saw all this, was slightly ludicrous. Just where we had reached the tank was an old man washing a not very clean cloth, and when he had done he washed himself and spat repeatedly in the water. He then went away, and within a minute a woman came there, stood almost in the identical spot the old man had stood a minute before, and filled two bright chatties with the water and took them home for drinking and cooking. She must of necessity have taken home some of the filth from the old man's clothes and a portion of his spittle to drink and cook with! What a repulsive idea! Now, what we have just seen passing under our eyes was taking place at various times of the day all round the tank, and not only all round this tank, but around the hundreds and thousands of tanks which are scattered over this fair continent of India. And this being the case, can we wonder for a moment at the rapidity with which an epidemic of cholera spreads through a community when once it makes its appearance in their midst? And yet how simple is the remedy! \* \* \* I do not by any means maintain water is the only means by which cholera is spread. \* \* \* I believe the air, clothes, food, especially drink of all sorts, besides water, may and do spread it; but I also believe that water is the chief means by which it is spread, especially in India, and that it is on account of the peculiar treatment water obtains in this country that India is the only country in the world subject to such frequently recurring and such terrible epidemics of this dread scourge.<sup>2</sup>

All the literature of good observers on cholera in India, and the leading conditions of its introduction into other countries during the ten years' interval since

<sup>1</sup> Voyage en Syrie et en Egypte, Vol. I, p. 175.

<sup>2</sup> Cholera and Water in India, by M. C. Furnell, M. D., F. R. C. S., Companion of the Indian Empire; Fellow of Madras University; late Surgeon-General and Sanitary Commissioner, Madras, etc. London, J. & A. Churchill, 1887.

the report of Dr. Furnell, confirm his observations. But besides cholera, the relation of the same conditions to other pestilential diseases should be kept in view. The report of the Madras municipality for 1891-'92 affords equally striking evidence of this relation. The death rate of the city of Madras for the year 1891 was 52.6 per 1,000 of the population. Of the 23,808 deaths which occurred that year, 66 were due to smallpox, 372 to measles, 6,731 to fevers, 4,573 to bowel complaints, and 1,916 to cholera, making a total of 13,658 from these causes, or 57 per cent of the whole; 5,843 were of infants under 1 year, being 437 per 1,000 of the population, or 30.19 of the children born alive. The explanation of these terrible figures is given in the report as follows:

An indifferent water supply, defective drainage, and over a considerable portion of the municipality no drainage at all, a porous soil loaded with organic impurity, a putrid and fluctuating subsoil water rising comparatively near the surface, want of open spaces in some parts of the town, crowded parcherries (villages) for the poor, overcrowded and ill-ventilated houses for the middle class (in many cases directly connected with the subsoil), water by wells in their interior, burial grounds and slaughter-houses in the city, and, lastly, the general social, conjugal, and religious habits and customs of the people.

In the district of the town in which the mortality was highest the unsanitary conditions are described as ghastly. "The first division, with a mortality of 72.8 per 1,000, contains some of the largest parcherries in the municipality, with wretched huts huddled together, in some cases on a soil that after a shower of rain forms a slough of liquid filth." The third division, with a death rate of 56.7, "has narrow streets of overcrowded and badly ventilated houses, most of which have wells in their interior connecting them with the subsoil water, which is here very putrid." It is in these divisions that the highest death rate from cholera occurred. The conditions of yellow fever are well known to comprise a high temperature, 70° F. and upward, in addition to the conditions common to pestilential diseases. As comprising these conditions in a concentrated degree, corresponding, more or less, with my own observations at Vera Cruz and other Mexican ports, several Central American and West Indian ports, seaports on the west coast of Africa, and at Memphis and New Orleans, in the United States, I quote a description of Havana in 1892, by Dr. Erastus Wilson, who has been a resident of that city for a number of years:

Havana occupies a peninsula formed by the Gulf of Mexico on the north and inletting of our bay or harbor on the east and south, terminating on that side in various lagoons and lowlands, through which several creeks meander and enter the bay in its shallow margins. Our slaughter-houses on one of these pour its blood and offal into these sloughs. In its topography its streets have not been constructed to regular grades, but have followed the original surface in various altitudes. A large proportion of our streets are yet unpaved, and in the poorer wards it is a common custom to throw slop water into the streets, where it frequently forms stagnant pools that fester in the sun and exhale noxious vapors. A clayey subsoil underlies its surface, and its habitations, without cellars, are in direct contact with its undrained, humid soil, without damp-proof courses to protect their walls from moisture, and these are regularly saturated and discolored with it 5 or 6 feet above the ground floors. The city has no system of sewers, and the night soil is almost universally accumulated within the rear part of the houses in the old midden closet, which is simply a hole in the ground, mostly without lining, and consequently its bottom and sides are permeable by the filth, and which, dissolved by the house slops and other domestic waters, soaks into the ground farther and farther, until the entire foundations of the houses are reeking and pestilent with these organic infusions, undergoing putrid fermentations and exhaling their death-dealing gases and microbes within all the habitations. Moreover these pestilential closets are usually adjoining the kitchens, and in near proximity to the sleeping apartments, which, in the houses of the poorer classes, are very imperfectly ventilated; and it is an inveterate custom of the people to close them persistently on the first approach of sickness, and particularly of febrile symptoms, heedless of professional advice to the contrary. Along the harbor side of the city wooden wharves are built upon piles, and several of the streets that descend to the bay have, loosely constructed with flat stones or bricks and lime

mortar, square drains of 1 foot, more or less, in size, and connecting their houses with them by similar conduits of smaller size, have set water-closets, and in this way, during many years, these conduits—by many called “sewers”—have been accumulating deposits of sewage, less than 3 feet under the surface of the streets, distributing their infiltrations, and pouring out some portions of them into the bay, which accumulate as pestilential mud under the wharves. Thus our population, familiarized with this state of uncleanness, are exceedingly careless in their methods of collecting their garbage, and possessing no public urinals, all these organic materials are spread about, and our abundant rains, at certain seasons, wash them into the low belt along the harbor. I have copied brief mortuary statistics of some of the affections that produce the highest death rates here, as follows: Out of our population of 200,000, I select the statistics of ten diseases that produced highest death rates in Havana in 1890 and 1891, in the order of their death rates, respectively: Pulmonary tuberculosis, 1,375, 1,384; lesions of heart and aorta, 633, 654; enteritis, 784, 579; pneumonia and bronchitis, 451, 429; yellow fever, 340, 349; cerebral congestion and hæmorrhage, 306, 291; meningitis, 298, 238; liver affections, 215, 197; pernicious fever, 164, 185; typhoid fever, 223, 172; smallpox, 12, 151.<sup>1</sup>

Typhus fever finds its conditions in dirt, privation, overcrowding, and cool or cold weather; conditions, excepting the last named, nearly identical with Oriental plague, of which disease, indeed, some observers regard it as being only a different type. “Jail fever,” “hospital fever,” “putrid fever,” and “ship fever” are its synonyms, and each one of these names suggests the conditions of its development, to which is added contagiousness proportional with their concentration. It would be an easy matter to multiply quotations from the history of pestilential diseases, with which all sanitarians are familiar, and to adduce numerous examples of approximate conditions when and wherever such diseases have prevailed in the United States, as elsewhere; particularly of the relations of a dirty soil and polluted water to the prevalence of typhoid fever and other intestinal diseases, not considered pestilential; but which, if estimated by their only true standard, the mortality from them in communities habitually subject to such conditions, is really more pestilential than any of the diseases against which quarantine restrictions are exercised, while the conditions which sustain them are those above all others most favorable to the introduction of cholera. It has been observed that in the several visitations of cholera to England “it has generally attacked those towns and houses which offered to it the best inducements to visit them in their filth, decaying refuse, crowded and dirty population, bad water, damp, polluted subsoil, or any other of those conditions which lead to bad health in a population, and which, when cholera is absent, afford an evidence of their existence by the prevalence of scarlet fever, smallpox, typhoid, and other fevers, measles, “whooping cough,” etc.,” to which diphtheria should be added as one of the most devastating of the group. Yet there are many communities that habitually indulge the conditions of these constantly recurring pestilential diseases, with which they have grown familiar, with never a thought apparently that the same conditions are a perpetual menace to the introduction, or it may be the revival, of the less common and exceptionally devastating pestilences. At the very time of writing this paper, my attention was arrested by a press announcement of an official report of the governor-general of Turkestan, which has recently been published in St. Petersburg, that that province has been severely visited by an epidemic of “black death,” which followed on the footsteps of cholera. It appeared suddenly at Askabad, and in six days killed 1,303 persons in a population of 30,000. “Black death” has long been known historically as a once common, deadly pestilence, which, like some other pestilences, superficial students have been wont to consider extinct. But the more attentively pestilential diseases are studied from the earliest records of them to the present time, the more evident it appears that not a single one of them has ceased to exist. The same and all exist to-day that ever

<sup>1</sup> Florida State Medical Society Transactions, 1892.

<sup>2</sup> Douglas Galton, C. B., D. C. L., etc., Journal of the Society of Arts, November 19, 1886.

have existed, and they are equally liable to occur again and again under favoring conditions.

My purpose in the foregoing quotations and interjections has been to emphasize the relation of pestilential diseases to the putrefaction of organic matter, the conditions which arrest, nourish, and propagate bacteria. Every student knows that the first bacterium ever discovered was in a drop of putrid water by Leeuwenhoeck, in 1675; but it was the discovery of no new thing. In the progress of bacteriological knowledge we have learned that bacteria are essential to the putrefaction of organic matter; that the existence of bacteria, therefore, is coëxtensive with putrefying material in time and place from the beginning, and that wherever putrescible matter exists; on the surface of the earth, in the soil or water, or in the air; there bacteria abound. But notwithstanding this beneficent function of bacteria, putrefaction, the process by which dead organic matter containing nitrogen is converted into food for plants, diligent investigation of their nature under divers circumstances has shown them to be, like other great tribes of plants, divisible into genera and species more or less antagonistic to each other, and that some of them are parasites dangerous to mankind and animals; these are the pathogenic germs of pestilential diseases; but, like the rest, they depend upon putrescible material for support and propagation. Like all living things, bacteria grow only at the expense of the food which they consume. Their viability depends more or less upon the presence of oxygen, though some can do without it; the presence or absence of moisture; the degree of temperature; the presence or absence of other agencies; antiseptics, germicides, etc.; and doubtless some conditions beyond our conception. But the spores of bacteria, the seeds, are, of all things viable, the most persistent. Indeed, so long as they do not germinate, do not encounter congenial conditions for development, so far as time is concerned, in the absence of destructive agencies, the spores of bacteria are practically immortal. They everywhere abide putrescible matter containing nitrogen, as their condition of development, maturity, and propagation. Hence, however true it may be that the adult microbe of cholera or that of any other disease may be destroyed by desiccation, or by sprinkling with some disinfecting solution, or that it is portable only by means of moist material, and not liable to be conveyed by clothing or rags, or borne on the wings of the wind; all such conditions are void when applied to the spores. I am aware that the cholera bacilli and some other pathogenic bacteria are devoid of spores, that they propagate exclusively by fission; yet even these are endowed with singularly enduring qualities, depending upon favorable conditions for vegetation. Moreover, as other vegetable organisms have their seasonal adaptations and favorable climates, so certainly have bacteria; and so, too, their spores or seeds, like the germs or seeds of other plants, may be quickened in unusual places under exceptional seasons. For example, typhus fever never prevails in warm climates, nor yellow fever in cold; yet all observers are familiar with the occasional occurrence of these diseases contrary to their habitats. Typhoid fever is well known to be a late summer and autumnal disease in temperate climates, yet the artificial climate of the dwelling often proves suitable to its development, when the germs are present. Moreover, of this disease in particular, like cholera, foul water is very far from being the only means of its distribution. The dust of dried excreta is ever liable to be carried in the air, to lodge in food or drink, and to be swallowed; and, with regard to the viability of the germ in the soil, Dr. S. Monckton Copeman cites the following case:

A man who had acquired enteric fever elsewhere brought it to a village. His evacuations were buried in the dung heap. Some weeks later five persons engaged in removing some of the dung were attacked by the disease. Their discharges were sunk deep in the heap. At the end of nine months it was completely cleared out by two workmen, one of whom fell ill of enteric fever and died.<sup>1</sup>

<sup>1</sup> Treatise on Hygiene, Stevenson and Murphy, Vol. I, p. 334.

Enormous numbers of bacteria have been found in the soil by various observers. Infusions made from manural, field, and garden earth, even though diluted a hundred times or more, still contain thousands of bacteria in every drop; and the soil and dust of streets always contain large numbers. Naegeli and Buckner demonstrated several years ago that the porous soil of the earth will yield germs existing in it to ascending currents of the air even when wet; which fact has a strong bearing upon the significance of the soil in the spreading of infectious diseases generally.<sup>1</sup>

Beumer, in experimental researches for bacteria in the soil, in 1886, obtained from a specimen of sandy humus taken from the depth of 3 meters, 45,000,000 to the gram; at 4 meters, 10,000,000; at 6 meters, 5,000,000. These specimens were obtained from the vicinity of hospitals at Greifswald. In a churchyard, at a depth of 4 meters, the number in one experiment was 1,152,000, and in another, 1,278,000.<sup>2</sup>

Frankel also has given special attention to the examination of undisturbed soil not in the immediate vicinity of dwellings.

The most important fact developed by Frankel's researches is that in virgin soil there is a dividing line at a depth of from three-quarters to one and one-half meters, below which very few bacteria are found, and that consequently the "ground-water region" is free from microorganisms, or nearly so, notwithstanding the immense numbers present.<sup>2</sup>

But neither of these investigators say anything about the kind of bacteria they found.

Manfredi has recently (1892) published the results of his extended investigations relating to the dust in the streets of Naples. The number of bacteria varied greatly in different parts of the city. In streets where the traffic was least and hygienic conditions the best the average number was 10,000,000 per gram. In dirty and busy thoroughfares the average was 1,000,000,000, and in certain localities the number was even five times as great as this. Injections into guinea pigs gave a positive result in 73 per cent of the animals experimented upon. Among the known pathogenic bacteria obtained in this way were the pus cocci (in eight), the bacillus tuberculosis (in three), the bacillus of malignant edema, and the tetanus bacillus.<sup>3</sup>

According to the investigations of Grancher and Richard, in 1889—

The superficial strata of the earth are exceedingly rich in pathogenic germs; at a certain depth there is a limit beyond which the number of germs rapidly diminishes, until they cease altogether. In the deep strata of the bacilliferous zone pathogenic species do not exist. Grancher and Deschamps have observed the arrest of the typhus bacillus at a depth of 50 centimeters. In the cultivated superficial strata there are fewer micrococci than bacilli. The bacilli exist in the soil chiefly as spores. Under this form they best resist destructive agents and remain latent for years, retaining their virulence. It is probable that the pathogenic bacilli germinate in the soil.

The cholera bacilli form numerous colonies at a depth of 3 meters during the months from August to October; from April to June, at a depth of 2 meters, there is no development, while at a depth of 1½ meters the bacillus vegetates. At least 2 per cent of humidity is necessary for the development of the germs. Soil rich in organic material is most favorable to this development. Causes of death of the pathogenic germs exist in the soil. The principal cause is desiccation. Koch and Duclaux have demonstrated that this is especially hurtful to the micrococci, and here, according to Koch, is the explanation of the fact that micrococci are relatively rare on the superficies of the soil. The cholera bacillus dies rapidly under exsiccation. Netter fixes three weeks as the extreme limit at which the exsiccated pneumococcus preserves its virulence.

The two most potent causes of destruction which the microbes encounter are the saprophytic bacilli and solar light. The saprophytic bacilli are in continual strife with the pathogenic microbes, and have generally the advantage. The bacillus of tetanus is exceptional, and may develop favorably in the presence of other species. Solar light is injurious to very many bacilli. According to Duclaux it is the

most universal means of sanitation, and the most economical and potent to which public or private hygiene can have recourse. The turning up of the soil liberates pathogenic germs, but when the soil is not disturbed for a long time a colossal germination frequently goes on. Exhumation frees the bacteria long latent in the soil; hence the epidemics that follow the turning up of the ground. Pathogenic germs leave the earth in many ways to attack men and animals. The soil which adheres to the body, to the feet of animals, and that which is carried by insects disseminates pathogenic germs. Currents of air transport superficial dust and so propagate the spores which resist exsiccation. Water also carries germs. Ordinarily subterranean waters are on a level with the bacteriological zone. Sometimes the zone is exposed by fissures or by openings made in the earth. The walls of a well are a prolongation of the superficies, and are favorable to the life of germs.<sup>1</sup>

The practical application of this summary is local sanitation. The more precise knowledge, acquired during recent years, of the specific entities of preventable diseases; of the part played by earth, air, and water in their dissemination, and of their essential dependence upon putrescible matter for their reception and growth, should not fail to stimulate sanitary effort everywhere against the conditions of their existence.

### DEMOGRAPHIC STATISTICS OF DISEASES FOR FIFTEEN CONSECUTIVE YEARS IN THE STATE OF MICHIGAN.

By HENRY B. BAKER, M. D., of Lansing, Mich.,

*Secretary of the State Board of Health of Michigan; ex-President of the American Public Health Association; member of the American Climatological Association, etc.*

#### DISEASES WHICH CAUSE MOST SICKNESS IN MICHIGAN.

*Order of prevalence of twenty-eight diseases in Michigan in the period of ten years, 1881 to 1890, and in each of those years, judging from the "per cent of reports" which stated the presence of each of the diseases, in connection with the reported "order of prevalence" when and where each disease was present.*

| 27     | Cerebro-spinal meningitis .....                    | 25                       | 26    | 25    | 25    | 26    | 26    | 26    | 25    | 25    | 24    | 22    |
| 28     | Smallpox .....                                     | 27                       | 28    | 28    | 28    | 27    | 27    | 27    | 27    | 26    | 26    | 26    |

In the years 1881-1883 intermittent fever, in the years 1884-'85 neuralgia, and in the years 1886-1890 rheumatism, caused most sickness. This does not imply that there was any increase in rheumatism, because, as indicated by this table, and as is proved in the diagram on that subject,

<sup>1</sup> La Revista Internazionale d'Igiene, of Naples, January, 1890.

intermittent fever decreased greatly. The "average disease" of those reported is included in this table as a standard by which to judge the fluctuations. In 1890 it may be seen that the "average disease" was higher than usual by about one-tenth. This was due to the unusual prevalence of "influenza," which, it may be seen, was twice as prevalent in 1890 as in the average year, the order in the average year being 8, while in 1890 it was 4. Pneumonia does not show any increase in 1890, nor any apparent change during the ten years.

MOVIMIENTO DEMOGRÁFICO DE BUENOS AIRES.

Por el Dr. SAMUEL GACHE,

*Presidente del Circulo Médico Argentino ; Medalla de Oro en el Concurso Sud-Americano de Medicina Celebrado en Buenos Aires en 1893 ; Delegado del Gobierno de la República Argentina en el Congreso Internacional de Higiene y Demografía, reunido en Paris, en 1889 ; Miembro de la Société Française d'Hygiène de Paris ; Oficial de Academia ; Médico del Hospital Ravosón.*

La ciudad de Buenos Aires, capital de la República Argentina, cuenta hoy 560,000 habitantes, sobre una extensión de 13,023,572 metros cuadrados, que es la del territorio del municipio. Remontando á los primeros tiempos del país y buscando hasta en la época de la fundación, encontramos que su población en el año 1580 era de 300 almas, y que en 1602 llegó á 500, para aumentar á 4,000 en 1664. Un siglo más tarde era de 24,205 ; en 1810 alcanzó á 46,000 ; en 1822, á 55,416, y á 76,000 en 1852. En 1864 era de 140,000 ; el censo de 1869 le dió 177,787 ; surbió á 195,262 en 1871 ; la epidemia de fiebre amarilla ocurrida en este año no detuvo el desarrollo de este movimiento progresivo, y la cifra total de habitantes era de 204,634 en 1872, es decir, arrojaba un aumento de 9,372 sobre la anterior, constituyendo un crecimiento relativo de 4.7. En 1875 tenía la ciudad 230,000 almas.

| Población. |         | Población.             |         |
|------------|---------|------------------------|---------|
| 1879 ..... | 257,440 | 1889 .....             | 523,452 |
| 1880 ..... | 270,000 | 1890 .....             | 547,144 |
| 1881 ..... | 289,925 | 1891 .....             | 535,060 |
| 1887 ..... | 433,375 | 1892 (diciembre) ..... | 554,713 |
| 1888 ..... | 455,167 | 1893 (junio) .....     | 560,000 |

La disminución que se observa en el año 1891 se explica por las causas de orden financiero que produjeron intensa crisis, y que obligaron á muchos á emigrar en busca de mejores condiciones de trabajo y economía que las que entonces ofrecía Buenos Aires. En 1892 la población ha aumentado meramente, y lo mismo se observa en 1893. El más poderoso factor con que hemos contado ha sido la inmigración que ha venido al país, y de la cual alguna buena parte se ha establecido en la ciudad, incorporándose á ella como fuerza y como elemento de producción y consumo.

El siguiente cuadro relativo al descenso de 1882-'91 hará comprender mejor el movimiento de entradas y salidas :

| Año.       | Inmigración. | Emigración. | Año.       | Inmigración. | Emigración. |
|------------|--------------|-------------|------------|--------------|-------------|
| 1882 ..... | 53,503       | 8,720       | 1887 ..... | 117,711      | 13,630      |
| 1883 ..... | 62,243       | 9,510       | 1888 ..... | 155,632      | 16,842      |
| 1884 ..... | 77,805       | 14,440      | 1889 ..... | 260,909      | 40,649      |
| 1885 ..... | 108,722      | 14,585      | 1890 ..... | 132,301      | 82,981      |
| 1886 ..... | 93,116       | 13,907      | 1891 ..... | 29,831       | 67,559      |

En 1892 la inmigración fué de 93,550 individuos ; la emigración de 55,282, lo que da un exeso de 38,468 en favor de la primera. Estos lijeros apuntes bastan para dar una idea general sobre la población de Buenos Aires, población cosmopolita constituida en su parte principal por el hijo del país y por los extranjeros numerosos, entre los cuales predominan los italianos, ocupando el segundo lugar los españoles, y los siguientes los franceses, ingleses, suizos, alemanes, etc. Exami-

nemos el movimiento demográfico de esta ciudad, y hagamos las comparaciones y deducciones á que se presten los datos que vamos á estudiar.

La natalidad en Buenos Aires nos ofrece la oportunidad de hacer algunas consideraciones sobre la fecundidad de la mujer argentina. Los matrimonios en nuestro país producen por lo general cinco hijos; y ha sido en virtud de esta abundante reproducción y de la grande inmigración que siempre ha acudido aquí, como ha podido la república ofrecer el aumento de su población que, siendo de 1,877,490 habitantes en 1869, ha llegado en 1893 á 4,500,000. Y por lo que se refiere á Buenos Aires, sabemos ya que en 1869 tenía 177,787 almas, y que hoy su número asciende á 560,000. Los nacimientos en los pueblos argentinos han alcanzado cifras elevadísimas; y para no citar sino dos casos nos referiremos á las ciudades de Buenos Aires y La Plata, qué con sus respectivas proporciones ocupan los dos primeros rangos en la natalidad de todo el mundo, exceptuando el Cairo. Pero debemos observar que si en el Cairo, según la estadística de 1891, la natalidad es mayor que en las dos ciudades referidas, siendo así el punto más favorecido al respecto, en cambio también tenemos allí una grandísima mortalidad, y resulta que si ocurren 51 nacimientos sobre 1,000 almas, mueren 50.6 individuos sobre 1,000, lo que da un aumento vegetativo sumamento pobre: 0.4 por 1,000, mientras que dicho aumento vegetativo en La Plata es de 23.85 (año 1890) y en Buenos Aires de 21.6. Este último dato resulta de los siguientes elementos:

|                                               |        |
|-----------------------------------------------|--------|
| Natalidad en 1891 .....                       | 24,591 |
| Natalidad por 1,000 habitantes .....          | 45.95  |
| Mortalidad absoluta .....                     | 13,041 |
| Mortalidad por 1,000 habitantes .....         | 24.32  |
| Aumento vegetativo absoluto .....             | 11,577 |
| Aumento vegetativo por 1,000 habitantes ..... | 21.6   |

Estas cifras revelan muy crecida cantidad de nacimientos, y exceptuando la de 118 por 1,000 habida en Buenos Aires en 1872, después de la epidemia de fiebre amarilla, jamás se ha visto proporción tan satisfactoria. La Plata, capital del Estado de Buenos Aires, ha dado en los ultimos años:

| Años.      | Natalidad<br>por 1,000<br>habitantes. | Mortalidad<br>por 1,000<br>habitantes. | Aumento<br>vegetativo<br>por 1,000<br>habitantes. |
|------------|---------------------------------------|----------------------------------------|---------------------------------------------------|
| 1884 ..... | 42.90                                 | 17.74                                  | 25.16                                             |
| 1885 ..... | 37.16                                 | 19.09                                  | 18.07                                             |
| 1886 ..... | 48.20                                 | 21.93                                  | 26.27                                             |
| 1889 ..... | 43.83                                 | 25.46                                  | 18.37                                             |
| 1890 ..... | 49.62                                 | 25.77                                  | 23.85                                             |

La extraordinaria natilidad de La Plata en 1890 coloca pues á esta hermosa ciudad en el primer rango por el aumento vegetativo de su población. Le sigue Buenos Aires con su aumento de 21.6 por mil, proporción que permite á ámbas figurar entre las principales del globo, en este sentido. En el decenio de 1882-91 han nacido en Buenos Aires:

| Años.       | Varones. | Mujeres. | Total.  | Ilegítimos. | Propor-<br>ción.   |
|-------------|----------|----------|---------|-------------|--------------------|
|             |          |          |         |             | <i>Por ciento.</i> |
| 1882 .....  | 5,276    | 5,201    | 10,477  | 839         | 8                  |
| 1883 .....  | 5,514    | 5,278    | 10,792  | 829         | 7.6                |
| 1884 .....  | 6,030    | 5,840    | 11,870  | 817         | 6.8                |
| 1885 .....  | 6,436    | 6,145    | 12,581  | 816         | 6.4                |
| 1886 .....  | 7,227    | 6,776    | 14,003  | 1,141       | 8.1                |
| 1887 .....  | 8,225    | 7,714    | 15,939  | 1,974       | 12.3               |
| 1888 .....  | 9,764    | 9,355    | 19,119  | 2,361       | 12.3               |
| 1889 .....  | 11,258   | 10,786   | 22,044  | 2,798       | 12.6               |
| 1890 .....  | 11,737   | 11,283   | 23,020  | 3,013       | 13                 |
| 1891 .....  | 12,512   | 12,079   | 24,591  | 3,342       | 13.5               |
| Total ..... | 83,979   | 80,457   | 164,436 | 17,930      | -----              |

Dividiendo estas cifras en dos períodos de cinco años, tenemos: De 1882 á 1886, nacimientos, 59,733, siendo de estos 4,442 ilegítimos; de 1887 á 1891, nacimientos, 104,703, de los cuales 13,488 son ilegítimos. Se ve por estas cifras que la ilegitimidad en el quinquenio de 1887 á 91 fué más de tres veces superior á la de 1882-86. Creemos encontrar las causas de esto en el hecho de las circunstancias excepcionales del país, con motivo de la gran crisis que lo ha conmovido y que hoy más que nunca se siente. La ilegitimidad está actualmente sostenida en Buenos Aires por la falta de dinero que actúa sobre todas las clases sociales y en especial las más bajas que son las que suministran el mayor contingente de este elemento.

La natalidad con relación á la población, y según sexos, de los nacidos, está expresada en el siguiente cuadro:

| Años.      | Población. | Nacimien-<br>tos. | Propor-<br>ción por<br>1,000 habi-<br>tantes. | Varones<br>para 100<br>mujers. |
|------------|------------|-------------------|-----------------------------------------------|--------------------------------|
| 1887 ..... | 437,875    | 15,939            | 36.40                                         | 106                            |
| 1888 ..... | 455,167    | 19,119            | 42                                            | 104                            |
| 1889 ..... | 523,452    | 22,044            | 42.10                                         | 104                            |
| 1890 ..... | 547,144    | 23,020            | 42.07                                         | 104                            |
| 1891 ..... | 536,060    | 24,591            | 45.95                                         | 103                            |

Conocido ya lo que sobre natalidad nos ofrece Buenos Aires y La Plata, hagamos algunas comparaciones entre estas y otras de las más importantes ciudades de Europa y América.

\* Madrid ha tenido en 1891 mayor mortalidad que natalidad.

Resumiendo, tenemos que deben colocarse en este orden las ciudades de mayor aumento vegetativo de su población: La Plata, Buenos Aires, Leipzig, Mulhouse, Magdeburgo, Varsovia, Montevideo, Hannover, Cardiff, Dresden, Nuremberg, Aberdeen, Birmingham, Bâle, Leeds, Lóndres, Berlin, Stockolmo, Dantzic, Franckfort, Zurich, Copenhague. Resulta pue que Buenos Aires es la región más favorecida en todo el globo, bajo el punto de vista de su natalidad y del crecimiento vegetativo de su población. Y consignaremos aquí como informe complementario, que en 1871, después de la epidemia de fiebre amarilla que en 1871 hizo 13,761 muertes, los nacimientos alcanzaron á la enorme proporción de 118 por 1,000 habitantes.

En cambio, las ciudades cuya mortalidad superó á la natalidad en el año 1891 son :

|              | Natalidad. | Mortalidad. |                  | Natalidad. | Mortalidad. |
|--------------|------------|-------------|------------------|------------|-------------|
| Madrid.....  | 17,507     | 17,563      | Rouen.....       | 2,771      | 3,762       |
| Madras.....  | 18,125     | 23,873      | Toulouse.....    | 2,661      | 3,113       |
| Burdeos..... | 5,273      | 6,364       | Bologna.....     | 3,637      | 3,677       |
| Lyon.....    | 8,461      | 9,371       | Florenzia.....   | 5,028      | 5,211       |
| Nancy.....   | 2,056      | 2,048       | Christiania..... | 2,588      | 3,013       |
| Nantes.....  | 2,653      | 3,313       | Bombay.....      | 15,543     | 23,784      |

Lima en 1884 presentó una natalidad de 3,845 y una mortalidad de 4,046; debe colocarse, pues, en la anterior categoría. Chile, por el contrario, ofrece una natalidad de 40 por 1,000 y una mortalidad de 32 por 1,000, lo que dá como aumento vegetativo 8 por 1,000. Terminando estas consideraciones diremos que en Chile sobre 1,000 nacimientos, 295 son ilegítimos; y que en Lima, sobre 3,820 nacimientos ocurridos el año 1884, fueron legítimos 1,759, y 2,061 ilegítimos, lo que da el promedio de 54 de estos por 46 de aquellos.

La nupcialidad ha pasado por muy diversas alternativas entre nosotros, y aunque actualmente no figura ella en la estadística demográfica con las cifras que sería conveniente para los fines ulteriores de la sociedad, es justo reconocer que ha experimentado un aumento considerable. De las investigaciones de Coni resulta que el número total de matrimonios verificados en Buenos Aires creció desde el año 1858 hasta el año 1873, y disminuyó gradualmente desde este último hasta 1877; y que á partir de esta fecha hasta 1881 se observa un estado estacionario. Tratando de explicar este fenómeno, podemos preguntar ¿por qué esta disminución en la cifra de los matrimonios y por qué este estacionamiento? Si queremos encontrar las respuestas, recordemos que la crisis política, iniciada en 1872 con motivo de los trabajos electorales, se prolongó después de 1874, no ya bajo ese carácter solamente sino también y de principal manera como crisis económica que obligó á todos los argentinos á reducir el monto de sus gastos.

En 1878 la proporción de matrimonios comparada con la población fué de 6.3 por 1,000; en 1879 de 6, y en 1880 de 6.1; proporción muy superior á la que corresponde al período de 1869-'77 en que fué 8.1 por 1,000. Pero á contar desde 1881, un fenómeno social se produce, íntimamente relacionado con el estado de abundancia del país, abundancia ficticia, debida á empréstitos exteriores y á desarreglos financieros cuyas consecuencias hasta los hijos de nuestros hijos tendrán que soportar. Los medios de obtener el dinero eran fáciles; los bancos ofrecían comodidades, y todos obtenían créditos. Con estos elementos, se comprende que los matrimonios fueran más frecuentes que nunca, y así se ha visto que en 1890 la nupcialidad fué de 10.13 por 1,000 habitantes.

El cuadro que va en seguida pone de manifiesto la marcha de la nupcialidad en los años que se indican.

| Años.     | Población. | Matrimonios. | Proporción por 1,000 habitantes. | Años.     | Población. | Matrimonios. | Proporción por 1,000 habitantes. |
|-----------|------------|--------------|----------------------------------|-----------|------------|--------------|----------------------------------|
| 1887..... | 437,875    | 3,428        | 7.82                             | 1890..... | 547,144    | 5,545        | 10.13                            |
| 1888..... | 455,167    | 4,498        | 9.88                             | 1891..... | 535,060    | 5,007        | 9.35                             |
| 1889..... | 523,452    | 4,159        | 7.94                             | 1892..... | 554,713    | 4,607        | .....                            |

Bajo este aspecto, Buenos Aires viene á estar más favorecida que San Petersburgo, cuya nupcialidad es de 6.4 por 1,000 habitantes, en tanto que en Roma es de 6; en Nápoles de 7.3; en Amberes de 8.6; siéndole superiores Paris con 11; Boston con 13.9. La proporción de matrimonios en Berlin es igual á la nuestra.

Vemos que en 1892 han disminuido los matrimonios, y debemos encontrar en esto una consecuencia lógica de la crisis que dificulta los gastos y aumenta la emigración.

La mortalidad en Buenos Aires en el quinquenio de 1887-1891 ha sido esta:

| Años.     | Mortalidad. | Propor-<br>ción por<br>1,000 habi-<br>tantes. |
|-----------|-------------|-----------------------------------------------|
| 1887..... | 12,894      | 27.59                                         |
| 1888..... | 13,482      | 27.16                                         |
| 1889..... | 16,039      | 28.15                                         |
| 1890..... | 17,721      | 29.9                                          |
| 1891..... | 14,332      | 24                                            |

Se ve pues que la proporción por 1,000 habitantes ha disminuido durante el año 1891, y la diferencia es considerable, si se comparan las cifras anteriores. Es así que Buenos Aires queda en mejores condiciones que las ciudades que se expresan con la relación de su mortalidad por 1,000:

|                 |      |                |      |                      |      |
|-----------------|------|----------------|------|----------------------|------|
| Havre.....      | 30.6 | Breslau.....   | 29.1 | Alejandro.....       | 38.1 |
| Marsella.....   | 30.5 | Dresden.....   | 29   | Madras.....          | 52.7 |
| Nancy.....      | 26.3 | Munich.....    | 27.6 | Milan.....           | 30   |
| Nantes.....     | 26.2 | Trieste.....   | 30.4 | Cairo.....           | 50.7 |
| Reims.....      | 26.1 | Barcelona..... | 30.7 | San Petersburgo..... | 28.5 |
| Rouen.....      | 35.3 | Madrid.....    | 36.4 | Bombay.....          | 28.9 |
| Dublin.....     | 26.1 | Lisboa.....    | 34.8 | Valencia.....        | 29.3 |
| Manchester..... | 26   | Moscú.....     | 37.3 | Florescia.....       | 28.5 |

Buenos Aires, con su mortalidad de 24 por mil correspondiente al año 1891, viene á estar igual á Paris, Nueva York, Brooklyn, Nuremberg, Lyon, Tolosa, Saint Etienne, etc. Las enfermedades que han contribuido á la mortalidad ocurrida en la capital argentina, con una cifra mayor de 100, son:

| Diagnósticos.           | 1887. | 1888. | 1889. | 1890. | 1891. | Totales. |
|-------------------------|-------|-------|-------|-------|-------|----------|
| Tuberculosis.....       | 1,041 | 1,069 | 1,245 | 1,168 | 814   | 4,337    |
| Neumonia.....           | 802   | 811   | 1,016 | 1,075 | 910   | 4,614    |
| Viruelas.....           | 1,299 | 657   | 185   | 2,198 | 276   | 4,615    |
| Difteria.....           | 753   | 1,113 | 646   | 802   | 510   | 3,794    |
| Gastro-enteritis.....   | 412   | 488   | 1,017 | 865   | 884   | 3,666    |
| Meningitis.....         | 599   | 666   | 721   | 770   | 820   | 3,576    |
| Lesiones cardiacas..... | 568   | 621   | 685   | 561   | 515   | 2,950    |
| Enteritis.....          | 318   | 422   | 614   | 447   | 568   | 2,369    |
| Bronco-neumonia*.....   | 303   | 303   | 642   | 583   | 520   | 2,351    |
| Fiebre tifoidea.....    | 280   | 388   | 509   | 628   | 408   | 2,213    |
| Atrepsia.....           | 327   | 352   | 540   | 390   | 457   | 2,066    |
| Bronquitis.....         | 281   | 342   | 479   | 472   | 436   | 2,010    |

\* Esta enfermedad se presentó como la neumonia en muchos casos después de la influenza, que fué epidémica en 1890, 1891 y 1892.

|                                 | 1887. | 1888. | 1889. | 1890. | 1891. | Totals. |

\* En 1886 se produjeron 530 muertes por el cólera.

Durante los años transcurridos de 1886 al 1891 inclusive, la mortalidad por enfermedades infecto-contagiosas ha sido :

|                       | 1886. | 1887. | 1888. | 1889. | 1890.* | 1891. |
|-----------------------|-------|-------|-------|-------|--------|-------|
| Tuberculosis .....    | 863   | 1,048 | 1,088 | 1,263 | 1,182  | 826   |
| Fiebre tifoidea ..... | 272   | 280   | 388   | 509   | 628    | 408   |
| Difteria .....        | 453   | 1,052 | 1,385 | 905   | 1,037  | 623   |
| Viruelas .....        | 536   | 1,299 | 657   | 185   | 2,198  | 275   |
| Escarlatina .....     | 60    | 62    | 17    | 17    | 26     | 11    |
| Sarampión .....       | 56    | 141   | 99    | 261   | 80     | 51    |
| Coqueluche .....      | 29    | 35    | 67    | 85    | 57     | 93    |

Veamos ahora el cuanto por ciento de la mortalidad general que representan estas cifras divididas por años :

|                       | 1886.              | 1887.              | 1888.              | 1889.              | 1890.              |
|-----------------------|--------------------|--------------------|--------------------|--------------------|--------------------|
|                       | <i>Por ciento.</i> | <i>Por ciento.</i> | <i>Por ciento.</i> | <i>Por ciento.</i> | <i>Por ciento.</i> |
| Tuberculosis .....    | 8.63               | 8.66               | 8.79               | 8.57               | 7.19               |
| Fiebre tifoidea ..... | 2.72               | 2.38               | 3.22               | 3.55               | 3.93               |
| Difteria y crup ..... | 4.53               | 8.94               | 11.49              | 6.32               | 6.49               |
| Viruelas .....        | 5.36               | 10.70              | 5.29               | 1.26               | 13.38              |
| Escarlatina .....     | 10.70              | .52                | .13                | .11                | .16                |
| Sarampión .....       |                    | 1.19               | .82                | 1.82               | .50                |
| Coqueluche .....      |                    | .29                | .56                | .59                | .36                |

La mortalidad general del año 1892 llegó á 14,612, y distribuida según los principales y más frecuentes diagnósticos, resulta :

|                                                |       |                           |       |
|------------------------------------------------|-------|---------------------------|-------|

|                                                |       | Fiebre tifoidea .....     | 214   |

Predominan las enfermedades infecciosas; y si es satisfactorio hoy comprobar que algunos han disminuido en frecuencia, es desconsolador, decir que otras aumentan. Por lo que respecta á la tuberculosis, los siguientes cuadros revelan su marcha en los últimos 22 años :

| Años.      | Mortali-<br>dad por<br>tubercu-<br>losis. | Mortali-<br>dad<br>general. | Pro-<br>porción.   | Años.      | Mortali-<br>dad por<br>tubercu-<br>losis | Mortali-<br>dad<br>general. | Pro-<br>porción.   |

\* Epidemia de fiebre amarilla que produjo 13,761 muertes.

Cifras de 14.8, 13.6 y 12.9 por ciento de mortalidad tuberculosa sobre la general, eran por cierto, muy crecidas y seriamente alarmantes. El aumento progresivo de la tuberculosis en un tiempo en que las enfermedades zimóticas tienden á disminuir en número con la sola excepción de la viruela que obedece á causas específicas, dice Rawson, solo puede ser explicado por un aumento de humedad en el subsuelo, en combinación con las demás causas de insalubridad.

Felizmente la proporción se ha reducido en los últimos años á menos de la mitad de lo que era en la época á que se refiere el ilustre higienista, época en que la población solo era de 220,000 habitantes. Así vemos que la tuberculosis que causaba el año 1876 el 14.8 por ciento de mortalidad, solo llegó á 8.63 y 8.66 en 1886 y 87, y quedó en 6.35 por ciento en 1890, con más de medio millón de almas dentro de la ciudad. El decrecimiento de sus cifras mortuorias es debido á las mejoras urbanas, á las obras de salubridad, al funcionamiento regular de muchas secciones de cloacas, á la desaparición del horror que inspiraba en otro tiempo la idea de entrar en los hospitales; á la buena asistencia que estos establecimientos ofrecen no solo á los pacientes que alojan, sino también á los que van á los consultorios que en ellos funcionan; á la acción siempre vigilante de los numerosos asilos donde se

recojen niños que, sin los cuidados que allí se prodigan, serían candidatos á la enfermedad; y hasta puede atribuirse á la mayor instrucción que hoy tiene el público respecto de muchas cosas.

Pero de todas las circunstancias favorables que han producido estos resultados, es ciertamente la primera el drenage. El Dr. Buchanan, observando los efectos de las obras de drenage en veinte y cinco ciudades de Inglaterra, informaba que en todas ellas la mortalidad general ha disminuido, en particular la causada por la fiebre tifoidea y la diarrea; pero en aquellas que habían sido provistas de grandes desagües, sin dárseles un sistema eficaz de drenage subsolar, ni la consunción pulmonar, ni las afecciones catarrales habían disminuido. El efecto inmediato del drenage subterráneo es secar el suelo permitiendo que el aire penetre y ocupe el lugar del agua al travez de la capa de tierra seca, acelerando así la oxigenación de las sustancias infectas que estaban en solución y poniendo el suelo en condiciones saludables. Además, este procedimiento secante ejerce una poderosa influencia sobre las capas atmosféricas inmediatamente contiguas al suelo y que forman el aire respirado por los habitantes. Se ha observado como regla invariable de fácil explicación por las leyes físicas, que las nieblas desaparecen ó disminuyen de un modo notable en las ciudades ú otras partes doquiera que la tierra ha sido secada por el drenage. De los dos hechos precedentes debe deducirse que el aumento de los tuberculosos corresponde al aumento de la humedad subsolar, unida á otras influencias depresivas, y que si deseamos poner límite á esta grave enfermedad, en la que lo que más debe temerse es el carácter hereditario, es necesario que forme parte de las obras que se prosiguen ahora, un sistema más completo de drenage subsolar, no solo para prevenir la invasión de nuevas masas de agua, sino para secar las que ahora contiene la tierra, y remover así la infección actual.<sup>1</sup> Otra consideración que hay que tener en cuenta, en favor de la positiva rebaja de la cifra de defunciones por tuberculosis, es la epidemia de influenza que en 1890-91 y '92 atacó á la población de Buenos Aires haciendo innumerables víctimas y despertando la irrupción de aquella.

Así, pues, de la cifra correspondiente á esos años, deberían deducirse muchos casos que han sido determinados por la acción de la grippe, haciendo estallar á aquella. Comparando la mortalidad de tuberculosis en Buenos Aires y en las más importantes ciudades del globo, se tiene el convencimiento de que es nuestra capital la que ofrece al respecto más favorable estadística; y para esto no hay más que recordar que mientras que á esta enfermedad corresponde el 6.33 por ciento de defunciones en Buenos Aires, según datos del año 1890, representa en el mismo año el 13.41 por ciento en Bruselas; el 13.30 por ciento en Berlin; el 12.25 por ciento en Baltimore; el 9.85 por ciento en Londres; el 22.10 por ciento en Madrid; el 19.51 por ciento en Paris; el 9.26 por ciento en Roma; el 17.51 por ciento en San Petersburgo; el 22.19 por ciento en Viena; el 14.82 por ciento en Copenhague.

La difteria ha sido muchas veces el azote de esta ciudad.

Basta dirigir la mirada sobre el siguiente cuadro para comprender la marcha que ella ha seguido entre nosotros:

| Años.     | Mortali-<br>dad<br>diftérica. | Años.     | Mortali-<br>dad<br>diftérica. | Años.     | Mortali-<br>dad<br>diftérica. |

<sup>1</sup> Buchanan, citado por Rawson.

El aumento de la mortalidad por difteria es considerable á partir del año 1884 en que fué de 253. En 1886 la vemos casi duplicar y llega á 493, para subir hasta 975 en 1887, y alcanzar en 1888 á 1381 que es la mayor hasta hoy. En 1889 disminuye una cuarta parte y vuelve á subir en 1890, para descender otra vez en 1891 y más aún en 1892.

Las cifras que venimos de examinar manifiestan malas condiciones en nuestra salubridad, y es sensible que á este respecto ofrezcamos estadística tan desfavorable. Ella se modificará, es seguro, con las medidas de desinfección á domicilio que hoy se adoptan, y con los consejos y prevenciones que se dirigen al público, pero mientras subsistan los conventillos, los tambos, las caballerizas, etc., en parages centrales, tendremos encima siempre el peligro común.

Con todo, podemos esperar que como disminuyó en 1891 y en 1892 por la acción de los medios higiénicos empleados, así continuará reduciendo sus estragos hasta colocarnos en posición más ventajosa. Los barrios donde mayor número de víctimas hace son los de los parroquias de San Cristobal, Balvanera, Santa Lucía y Pilar, los más favorecidos por una abundante población menesterosa y falta de comodidades. Por las inmediaciones de la plaza "Once de Setiembre," Constitución y Cementerio del Sur, ella ha sido frecuente, y es en esos parajes donde se encuentran muchas de las condiciones propicias al desarrollo de la enfermedad.

El otoño y el invierno son las estaciones en que recrudece con marcada intensidad. Si hacemos comparaciones entre la mortalidad diftérica de Buenos Aires y otras ciudades de las que más alta la presentase, tenemos sobre 100 defunciones generales en los años 1886-90:

|                   | 1886. | 1887. | 1888. | 1889. | 1890. |                 | 1886. | 1887. | 1888. | 1889. | 1890. |
|-------------------|-------|-------|-------|-------|-------|-----------------|-------|-------|-------|-------|-------|
| Buenos Aires..... | 4.53  | 8.94  | 11.49 | 6.32  | 6.49  | Copenhague..... | 4.16  | 5.11  | 5.2   | 6     | 7.45  |
| Berlin.....       | 4.90  | 4.67  | 3.7   | 3.72  | 4.78  | Marsella.....   | 4.4   | 4.77  | 4.3   | 3.36  | 5.20  |
| Brooklyn.....     | 7.1   | 8.96  | 5.4   | 7.44  | 6.56  | Madrid.....     | ----- | ----- | 6.7   | 3.76  | 3.44  |
| Filadelfia.....   | 5.3   | 4.01  | 1.7   | 3.54  | 4.18  | Chicago.....    | ----- | 9.12  | 7.7   | 8.90  | 5.77  |

Son estas ciudades cuyas estadísticas conocidas revelan más alta mortalidad diftérica, y vemos que entre ellas Buenos Aires sobresale desgraciadamente por una alta proporción sobre el número total de aquella con relación á las defunciones generales.

Las viruelas han producido verdaderas epidemias en Buenos Aires hasta hace pocos años, y en especial con motivo de la conquista del desierto, que dió por resultado la incorporación de muchos miles de indios, en las casas como servidores, en los cuarteles como soldados, etc.; y es bien conocida la predisposición y facilidad que estos ofrecen á la invasión variólica.

Después de varios años en que estuvo relativamente apagada mediante la profilaxia de la vacuna, las viruelas recrudecieron en 1887 y su mortalidad se dobló con relación á la del anterior; se redujo á la mitad en 1888; descendió á 185 al siguiente y en 1890 tomó nuevo incremento, produciéndose 2,198 defunciones. Hagamos notar que en este año y con motivo de la revolución de julio, vinieron á la ciudad batallones de diferentes puntos, lo que es fácil suponer contribuyó á la difusión de la enfermedad por el hacinamiento y otras circunstancias. En 1891 la mortalidad por viruelas solo fué de 275 y en 1892 de 30. La amplia difusión de la vacuna ha producido estos benéficos resultados al extremo de reducir la mortalidad de viruelas á cifras exiguas.

El siguiente cuadro es bien elocuente:

*Vacunación y viruelas.*

| Años.     | Vacunados<br>y reva-<br>cunados. | Mortali-<br>dad por<br>viruelas. | Años.     | Vacunados<br>y reva-<br>cunados. | Mortali-<br>dad por<br>viruelas. |
|-----------|----------------------------------|----------------------------------|-----------|----------------------------------|----------------------------------|
| 1883..... | 6,906                            | 1,510                            | 1888..... | 941                              | 657                              |
| 1884..... | 3,006                            | 142                              | 1889..... | 18,349                           | 185                              |
| 1885..... | 5,600                            | 736                              | 1890..... | 38,247                           | 2,198                            |
| 1886..... | 4,205                            | 536                              | 1891..... | 13,056                           | 275                              |
| 1887..... | 2,726                            | 1,267                            | 1892..... | 19,274                           | 30                               |

La fiebre tifoidea ha sido en todo tiempo conocida en Buenos Aires, y ha producido epidemias especialmente limitadas á barrios donde las gentes beben agua de pozo y viven en malas condiciones de higiene. Conviene decir que en tales casas las letrinas están inmediatas á los pozos, y que las filtraciones son fáciles. Si á los enfermos tifoideos en los hospitales se les pregunta acerca de la procedencia del agua de bebida, responden, de pozo. Y aunque puedan emplear las aguas corrientes, dejan estas por aquella. El servicio de aguas corrientes está bien establecido en Buenos Aires; corresponde próximamente 190 litros por habitante en las 24 horas; su composición es buena; no ofrecen peligro de infección “porque, dada su pobreza en materia orgánica, las bacterias patógenas no pueden vivir en ellas;” además, “son las más puras y mejores de la población,” y “la cantidad de bacterias que contienen nada tiene de anormal.” (Arata.)

Entre las epidemias de fiebre tifoidea, la del año 1867 se recuerda como muy mortífera. Produjo 600 muertes sobre una población de 177,787 habitantes. Al mismo tiempo que esta invadió el cólera. Desde 1869 hasta 1887, la tifoidea ha actuado entre nosotros produciendo más ó menos víctimas, pero á contar de este último año su mortalidad ha sido considerable con relación á una época en que precisamente debería suceder lo contrario, dado el adelanto de la higiene pública y la extensión de la bacteriología. En 1891 disminuye algo, y esta disminución se acentúa mucho en 1892 como resultado de las medidas adoptadas para mejorar las condiciones sanitarias, combatiendo las causas de insalubridad y arbitrando los medios hoy tan conocidos de una profilaxia segura.

Debido á la acción del director de la asistencia pública, Dr. Emilio R. Coni, ha sido posible contener la invasión de la enfermedad y reducirla en 1892 á cifras ciertamente menores que las de años anteriores. En este último año solo murieron 214 tifoideos en una población de 550,000 habitantes, casi lo mismo que en 1885 sobre 390,000 almas.

El decenio de 1883-92 ha suministrado la siguiente mortalidad tifoidea:

| Año.      | Mortali-<br>dad. | Propor-<br>ción por<br>100,000 ha-<br>bitantes. | Año.      | Mortali-<br>dad. | Propor-<br>ción por<br>100,000 ha-<br>bitantes. |
|-----------|------------------|-------------------------------------------------|-----------|------------------|-------------------------------------------------|
| 1883..... | 180              | 55                                              | 1888..... | 388              | 83                                              |
| 1884..... | 193              | 58                                              | 1889..... | 509              | 83                                              |
| 1885..... | 209              | 55                                              | 1890..... | 628              | 117                                             |
| 1886..... | 272              | 69                                              | 1891..... | 417              | 79                                              |
| 1887..... | 279              | 65                                              | 1892..... | 214              | 42                                              |

Sobre 100 defunciones generales corresponden á la fiebre tifoidea en Buenos Aires, en los años que se expresan, estas proporciones: En 1886, 2.72; en 1887, 2.38; en 1888, 3.22; en 1889, 3.55; en 1890, 3.93; en 1891, 2.89; en 1892, 1.47.

En 1890 alcanza esta enfermedad su mayor desarrollo aquí: 628 muertes sobre un total de 17,721 defunciones, esto es, 3.93 por ciento, la cifra más alta hasta hoy. En 1891, desciende á 417, y en 1892 el descenso se acentúa mucho más y la cantidad

de tifoideos fallecidos solo llega á 214, esto es, 1.47 por ciento de la mortalidad general. En los últimos años, los barrios más visitados por esta enfermedad han sido los inmediatos al puerto entonces en construcción, dársena sur, Boca, y en general toda la ribera y la parte sudoeste de la ciudad, sin descuidar los arrabales donde habita gente pobre y desaseada.

Las estaciones en que mayor número de individuos ataca son el otoño y el verano; si bien en invierno también invade como lo hemos visto en 1891-92. En esta predilección por ciertas estaciones podemos referir verdadera influencia á las lluvias de la primavera, las que favoreciendo la acción del verano preparan el terreno para que la enfermedad estalle. Esto se comprobó con ocasión de la epidemia tifoidea del año 1869, sobrevenida en dicha estación después de grandes lluvias.

En la "Casa de aislamiento" se asisten los individuos atacados de enfermedades infecciosas, y allí son trasladados los tifoideos que no pueden asistirse en sus domicilios. En el último año entraron en dicho hospital 130 de estos enfermos (tifoideos) y murieron 32. La mortalidad producida por estos representó el 14 por ciento en el año 1890 sobre lo general, y en 1891 el 13 por ciento.

La neumonía ha sido en 1892 desastrosa en intensidad y frecuencia. Sobre 14,612 defunciones generales le corresponden 1,144 (13 por ciento). Ha sido mucho peor que la tuberculosis (1,022) que siempre ha constituido un factor importante en la mortalidad.

Si á los 1,144 neumónicos agregamos los 936 fallecidos por bronco-neumonía, la proporción sube considerablemente. Y aquí entra de una manera positiva la influencia de la gripe que ha dominado especialmente en 1892 como en 1891, complicando muchos estados mórbidos, determinando las bronco-neumonías infecciosas y haciendo estallar la tuberculosis ó poniendo al organismo en condiciones de fácil receptividad.

Las cifras relativas á la neumonía y á la bronco-neumonía que acabamos de dar, son las más altas hasta ahora anotadas entre nosotros, y así vemos que en los últimos años han sido:

|                      | 1887. | 1888. | 1889. | 1890. | 1891. | 1892. |
|----------------------|-------|-------|-------|-------|-------|-------|
| Neumonía.....        | 802   | 811   | 1,016 | 1,075 | 910   | 1,144 |
| Bronco-neumonía..... | 303   | 303   | 642   | 583   | 520   | 936   |

Se recordará siempre de los inviernos de 1891-92 en que la influenza no dejó casa sin atacar, existiendo familias enteras que la sufrían al mismo tiempo. Esto que fué de observación común en la clínica privada, era más evidente en los hospitales, á los que acudían en cantidades extraordinarias los enfermos de gripe, neumonía y bronco-neumonía.

La influenza presente entre nosotros desde 1890 no ha dejado de hacer víctimas, y por el contrario ha contribuido poderosamente al aumento de las defunciones anuales. Sin contar las diversas complicaciones que la acompañan ha producido 182 muertes en 1892. Su acción ha sido evidente, incontrastable, y la intensidad del ataque tan grande, muchas veces, que hemos visto enfermos revolcarse en la cama buscando alivio á los dolores atroces que los atormentaban.

En la gran mayoría de los casos las formas benignas han predominado, pero en cambio ahí están las enfermedades del aparato respiratorio con su mortalidad en aumento en los últimos años que han sido los invadidos por la gripe, atestiguando sus consecuencias. Las cifras de neumonías y bronco-neumonía son espantosas. Aparte de los padecimientos anotados como favorecidos por ella, está la tuberculosis que el ultraje de la influenza despierta en el organismo de antemano debilitado.

Las modalidades más raras se han presentado á la observación clínica, y después de las complicaciones pulmonares que han sido las más comunes, las nerviosas han asumido un carácter acentuado de tenacidad y persistencia. En algunos casos se ha visto la fiebre tifoidea declararse y definirse bien en el curso de la enfermedad en cuestión.

En el invierno actual (1893) ella ha atacado muchas personas, pero todo hace presumir que no tendrá ni la marcha ni la fuerza de años anteriores.

La escarlatina disminuye notablemente al punto de que durante el año 1892 su mortalidad fué solo de 12.

El sarampión en cambio se ha mantenido elevado algunos años, y en 1892 su cifra no ha dejado de ser crecida. Comparemos la mortalidad de estas dos enfermedades:

|                  | 1887. | 1888. | 1889. | 1890. | 1891. | 1892. |
|------------------|-------|-------|-------|-------|-------|-------|
| Escarlatina..... | 62    | 17    | 17    | 26    | 11    | 12    |
| Sarampión.....   | 141   | 99    | 261   | 80    | 54    | 188   |

La coqueluche aumenta aunque sus proporciones no son grandes. Sin embargo su mortalidad que fué de 35 en 1887, subió á 67 en 1888, á 85 en 1889, á 57 en 1890, á 91 en 1891; pero en 1892 se redujo á 29.

Los nacido-muertos en 1892 han alcanzado la cantidad de 1,271, inferior á la de los años 1888, 1890, y 1891.

Su proporción con la mortalidad general está representada en el siguiente cuadro:

|           | Nacido<br>muertos. | Morta-<br>lidad<br>general. | Propor-<br>ción por<br>100<br>defun-<br>ciones<br>gene-<br>rales. |           | Nacido<br>muertos. | Morta-<br>lidad<br>general. | Propor-<br>cion por<br>100<br>defun-<br>ciones<br>gene-<br>rales. |
|-----------|--------------------|-----------------------------|-------------------------------------------------------------------|-----------|--------------------|-----------------------------|-------------------------------------------------------------------|
| 1887..... | 775                | 12,117                      | 5.9                                                               | 1890..... | 1,304              | 16,417                      | 7.6                                                               |
| 1888..... | 1,115              | 12,367                      | 8.8                                                               | 1891..... | 1,312              | 13,014                      | 10.1                                                              |
| 1889..... | 1,303              | 14,736                      | 8.8                                                               | 1892..... | 1,271              | 14,612                      | 8.7                                                               |

La mortalidad infantil, por las elevadas cifras que desgraciadamente la representan, ofrece notorio contraste con el rápido progreso que tanto ha levantado á Buenos Aires en los últimos 15 años.

El hecho observado en todas partes se comprueba entre nosotros; los niños menores de un año pagan el mayor tributo en la mortalidad infantil, y anticipémonos á decir que mientras mueren de 1 año 36,568, como sucedió de 1875 á 1890 en Buenos Aires, mueren 16,653 de 1 á 2 años en el mismo término de 15 años.

La proporción de mortalidad para los niños de menos de 1 año establece que ella es de 17 por ciento entre nosotros, en tanto que en muchos países de Europa llega hasta 34, más de la tercera parte de los nacidos. El siguiente cuadro revela el número de nacimientos, niños muertos de 0 á 2 años, y sobrevivientes desde 1875 á 1890:

| Años.       | Nacimien-<br>tos, no<br>contando<br>nacido-<br>muertos. | Niños<br>muertos<br>de 0 á 1<br>año. | Sobrevi-<br>vientes. | Niños<br>muertos<br>de 1 á 2<br>años. | Sobrevi-<br>vientes. |
|-------------|---------------------------------------------------------|--------------------------------------|----------------------|---------------------------------------|----------------------|
| 1875.....   | 9,945                                                   | 1,939                                | 8,006                | 927                                   | 7,079                |
| 1876.....   | 9,647                                                   | 1,463                                | 8,184                | 521                                   | 7,663                |
| 1877.....   | 9,530                                                   | 1,636                                | 7,894                | 644                                   | 7,250                |
| 1878.....   | 9,656                                                   | 1,540                                | 8,116                | 571                                   | 7,545                |
| 1879.....   | 10,616                                                  | 1,621                                | 8,995                | 920                                   | 8,075                |
| 1880.....   | 10,077                                                  | 1,582                                | 8,495                | 761                                   | 7,734                |
| 1881.....   | 10,221                                                  | 1,557                                | 8,664                | 729                                   | 7,935                |
| 1882.....   | 11,137                                                  | 1,671                                | 9,466                | 921                                   | 8,545                |
| 1883.....   | 11,434                                                  | 1,986                                | 9,438                | 912                                   | 8,526                |
| 1884.....   | 12,551                                                  | 2,117                                | 10,434               | 1,022                                 | 9,412                |
| 1885.....   | 13,839                                                  | 2,338                                | 11,501               | 928                                   | 10,573               |
| 1886.....   | 14,003                                                  | 2,745                                | 11,258               | 889                                   | 10,369               |
| 1887.....   | 15,939                                                  | 3,002                                | 12,937               | 1,456                                 | 11,481               |
| 1888.....   | 19,119                                                  | 3,291                                | 15,828               | 1,315                                 | 14,513               |
| 1889.....   | 22,044                                                  | 3,967                                | 18,077               | 2,280                                 | 15,797               |
| 1890.....   | 23,020                                                  | 4,113                                | 18,907               | 1,857                                 | 17,050               |
| Totals..... | 212,768                                                 | 36,568                               | 176,200              | 16,653                                | 159,547              |

Más adelante analizaremos estas cifras que son en sí muy desconsoladoras.

De las investigaciones del Dr. Coni resulta que desde 1875 á 1890 han muerto 53,221 niños de 0 á 2 años, clasificados así:

|                                                                             |        |                                                 |        |
|-----------------------------------------------------------------------------|--------|-------------------------------------------------|--------|
| Aparato digestivo.....                                                      | 12,320 | Enfermedades de la nutrición <sup>3</sup> ..... | 78     |
| Aparato respiratorio.....                                                   | 10,002 | Enfermedades génito-urinarias.....              | 184    |
| Aparato circulatorio.....                                                   | 298    | Enfermedades de la piel.....                    | 164    |
| Enfermedades del sistema nervioso.....                                      | 8,104  | Enfermedades de la sangre <sup>4</sup> .....    | 46     |
| Enfermedades infecciosas ó localiza-<br>ciones típicas <sup>1</sup> .....   | 10,500 | Sin clasificación.....                          | 7,391  |
| Enfermedades infecciosas ó localiza-<br>ciones variables <sup>2</sup> ..... | 4,134  | Total.....                                      | 53,221 |

El predominio de las enfermedades infecciosas es notable; las 14,634 defunciones que ellas han producido representan el 27.4 por ciento y están así divididas según diagnósticos:

|                                                                                        |       |                          |        |
|----------------------------------------------------------------------------------------|-------|--------------------------|--------|
| Tétanos.....                                                                           | 4,983 | Disenteria.....          | 279    |
| Viruela.....                                                                           | 3,356 | Fiebre tifoidea.....     | 244    |
| Difteria y crup.....                                                                   | 2,529 | Erisipela.....           | 172    |
| Sífilis.....                                                                           | 802   | Escarlatina.....         | 127    |
| Tuberculosis (escrofulosis, tabes mesen-<br>térica, meningitis tuberculosa, etc.)..... | 801   | Varias enfermedades..... | 25     |
| Sarampión.....                                                                         | 759   | Total.....               | 14,634 |
| Coqueluche.....                                                                        | 557   |                          |        |

Las del aparato digestivo son también frecuentes, 12,320 (23 por ciento), están así clasificadas:

|                       |       |                            |        |
|-----------------------|-------|----------------------------|--------|
| Gastro-enteritis..... | 4,233 | Hepatitis.....             | 97     |
| Enteritis.....        | 2,838 | Gastritis.....             | 86     |
| Atrepsia.....         | 2,484 | Fiebre gástrica.....       | 82     |
| Entero-colitis.....   | 1,314 | Colerina.....              | 57     |
| Colera infantil.....  | 359   | Diversas enfermedades..... | 394    |
| Indigestión.....      | 249   | Total.....                 | 12,320 |
| Diarrea.....          | 126   |                            |        |

Las del aparato respiratorio, 10,002, representan el 18.7 por ciento y son estas:

|                          |       |                                  |        |
|--------------------------|-------|----------------------------------|--------|
| Neumonía.....            | 5,140 | Pleuro-neumonía y pleuresia..... | 152    |
| Bronquitis.....          | 2,575 | Diversas.....                    | 110    |
| Bronco-neumonía.....     | 1,575 | Total.....                       | 10,002 |
| Laringitis.....          | 140   |                                  |        |
| Congestión pulmonar..... | 130   |                                  |        |

<sup>1</sup> Sarampión, escarlatina, tifus exantémico, erisipela, herpes, viruelas, reumatismo articular, fiebres palúdicas, coqueluche, gripe, parotiditis, fiebre tifoidea, disenteria, cólera asiático y nostras, fiebre amarilla, tétanos y meningitis cerebro-espinal.

<sup>2</sup> Tuberculosis en sus diferentes formas, escrofulosis, sífilis, lepra, difteria, pústula maligna y rábia.

<sup>3</sup> Raquitismo.

<sup>4</sup> Leucocitemia, anemia perniciosa progresiva, clorosis, púrpura, hemofilia y escorbuto.

Las del sistema nervioso abarcan 8,104 (15 por ciento) y son las siguientes:

|                                     |       |                           |     |
|-------------------------------------|-------|---------------------------|-----|
| Meningitis .....                    | 5,248 | Hidrocefalia .....        | 232 |
| Congestión y derrame cerebral ..... | 1,172 | Meningo-encefalitis ..... | 172 |
| Eclampsia .....                     | 978   | Encefalitis .....         | 143 |

De los cálculos mensuales se deduce que la mortalidad infantil entre nosotros ha llegado hasta 52 por ciento de la general, pero oscila al derredor de 44 y 46 por ciento. Estos datos son por demás alarmantes, y deben llamar la atención de las autoridades. En nuestra opinión las causas que obran para producir la gran cifra de mortalidad infantil en Buenos Aires son principalmente dos: el poco cuidado que muchas gentes tienen en la alimentación de los niños, y la ignorancia de parte de los encargados de administrarla. Coni (de Buenos Aires) dice que si el abandono de la lactancia materna ejerce una poderosa influencia sobre la mortalidad infantil, la alimentación prematura—causa de un gran número de enfermedades—suministra también á la mortalidad un contingente igual.

Las familias y especialmente las de las clases pobres tienen la perniciosa costumbre de dar á los niños en la primera edad alimentos de toda naturaleza, sin preocuparse si estos son poco ó no son nada asimilables. De allí, alteraciones profundas en el aparato digestivo (vómitos, diarreas, etc.), alteraciones consideradas de poca importancia y encerrando á menudo el principio de graves enfermedades. Las madres que recurren á la lactancia artificial, medida justificada ó no, ignoran casi siempre ciertos preceptos, tan sencillos como indispensables, para que esta manera de alimentación no ocasione malos resultados.<sup>1</sup>

Un hecho averiguado en el dominio de la patología infantil es la influencia de la alimentación, cuando esta se hace insuficiente ó defectuosa; y para salvar en lo posible este inconveniente se han establecido en Paris, Loussane, Berlin, y Stockolmo servicios especiales, habiéndose comprobado en la primera una disminución de las enfermedades del aparato digestivo en la primera infancia, desde que se cuida prolijamente de evitar la falsificación de la leche, sin que por lo que respecta á las dos últimas ciudades se pueda afirmar nada en absoluto, si bien hay que esperar buenos resultados de las medidas adoptadas.

En Francia existe una práctica que sería muy benéfica si las madres de familia se dieran el trabajo de obedecerla. Consiste ella en distribuir en las oficinas del registro civil, á los padres de los niños cuyos nacimientos se inscriben, un folleto conteniendo instrucciones sobre la higiene de la primera infancia; pero á menudo sucede que tales instrucciones no son leídas, y por consiguiente quedan ignoradas.

En cuanto á las estaciones en que mueren más niños, tenemos que las 53,221 defunciones de 0 á 2 años, producidas de 1875 á 1890, han ocurrido así:

|                 |        |                |        |
|-----------------|--------|----------------|--------|
| Verano .....    | 14,808 | Invierno ..... | 12,761 |
| Primavera ..... | 14,088 | Otoño .....    | 11,564 |

Es el verano la estación en que mayor número de muertes tiene lugar y aquí hay que considerar la acción del calor, la leche muchas veces alterada, las frutas, las malas aguas, los cambios de temperatura, y en muchos casos la falta de cuidado y de aseo. No hay más que penetrar en un conventillo para ver el triste espectáculo que ofrecen los niños, y comprender así la causa de la enorme mortalidad de la primera infancia. La ignorancia y el abandono de los padres son los elementos que más intervienen en este lúgubre cuadro.

En el mismo término (1885-1890) han muerto 3,858 niños de 5 á 10 años, así clasificados:

|                                              |       |                                     |       |
|----------------------------------------------|-------|-------------------------------------|-------|
| Aparato digestivo .....                      | 222   | Enfermedades genito-urinarias ..... | 87    |
| Aparato respiratorio .....                   | 385   | Enfermedades de la piel .....       | 6     |
| Aparato circulatorio .....                   | 56    | Enfermedades de la sangre .....     | 11    |
| Enfermedades del sistema nervioso .....      | 398   | Sin clasificación .....             | 207   |
| Infecciones á localizaciones típicas .....   | 926   |                                     |       |
| Infecciones á localizaciones variables ..... | 1,547 | Total .....                         | 3,858 |
| Enfermedades de la nutrición .....           | 13    |                                     |       |

<sup>1</sup> Coni: Causes de la morbidité et de la mortalité de la première enfance à Buenos Aires, 1886.

Aún cuando el exámen comparativo con otros países nos sea favorable, debemos reconocer que estamos lejos aún de presentar datos que sean consoladores, y es satisfactorio decir que en este sentido se comprueba un movimiento que más tarde dará excelentes resultados.

El Patronato de la Infancia, institución creada á semejanza de algunas que existen en Europa, tiende en sus fines primordiales á disminuir los estragos de las enfermedades infantiles, fundando maternidades y asilos, consultorios médicos, vigilando la lactancia mercenaria, las fábricas donde los menores trabajan, y tratando por todos los medios posibles de poner la salud de estos en buenas condiciones para que se desarrollen fuertes de cuerpo y con el espíritu de trabajo que necesitamos para prosperar. No serán inútiles algunas consideraciones sobre el tétano infantil, muy frecuente en otro tiempo en Buenos Aires, y cuya disminución se acentúa hoy felizmente. Los datos del siguiente cuadro hasta 1890 pertenecen al Dr. Coni, y revelan la cifra de mortalidad que ella produce:

|      |     |      |     |      |     |
|------|-----|------|-----|------|-----|
| 1875 | 436 | 1881 | 237 | 1887 | 183 |
| 1876 | 412 | 1882 | 241 | 1888 | 265 |
| 1877 | 430 | 1883 | 286 | 1889 | 398 |
| 1878 | 372 | 1884 | 264 | 1890 | 292 |
| 1879 | 308 | 1885 | 302 | 1891 | 319 |
| 1880 | 255 | 1886 | 302 | 1892 | 265 |

En estas cifras predomina el sexo masculino. En cuanto al momento de la vida en el cual la mortalidad es más crecida, es entre la primera y la segunda semana del nacimiento; en este período se produce más de la mitad de las defunciones que corresponden al tétano. El otoño y el invierno son las estaciones en que más niños mueren por esta enfermedad.

Antes de las teorías microbianas, el létano era en Buenos Aires de una frecuencia aterradora. Hoy que las parteras reciben buena instrucción práctica, y que los beneficios de la asepsia se desparraman y multiplican, se reducen notablemente sus víctimas. Siendo como es, el resultado de una infección (bacilus Nicolaier) la curación antiséptica y la conservación de una absoluta higiene se imponen.

La proporción de mortalidad infantil al año, en varios países, por 1,000 habitantes, es esta:

|                    | 0 á 1<br>año. | 1 á 5<br>años. | Sobre<br>1,000<br>habitan-<br>tes de<br>todas<br>edades. |              | 0 á 1<br>año. | 1 á 5<br>años. | Sobre<br>1,000<br>habitan-<br>tes de<br>todas<br>edades. |
|--------------------|---------------|----------------|----------------------------------------------------------|--------------|---------------|----------------|----------------------------------------------------------|
| Italia             | 234.9         | 66.6           | 30.1                                                     | Suiza        | 220.1         | 23.1           | 23.8                                                     |
| Francia            | 179.8         | 27.5           | 22.3                                                     | Bélgica      | 176.3         | 34             | 24.6                                                     |
| Inglaterra y Gales | 167.5         | 32.6           | 22.2                                                     | Países Bajos | 195.5         | 30.3           | 22.8                                                     |
| Escosia            | 121.6         | 159.8          | 22.6                                                     | Suecia       | 127.9         | 26.1           | 17.5                                                     |

\* De 0 á 5 años.

Según este cuadro Grecia é Irlanda presentan la estadística mortuoria infantil más reducida, en tanto que Wurtemberg, Baviera y Sajonia ofrecen cifras muy elevadas. Sabemos ya que en Buenos Aires la cifra de niños de 0 á 1 año que mueren es de 17 sobre 100 nacidos vivos, lo que le asigna condiciones mejores que muchos países de Europa, en donde ese número es mayor. De los sobrevivientes al primer año en Buenos Aires muere el 9 por ciento en el segundo año. Desde el año 1885 á 1890, inclusive, han fallecido aquí 5,386 niños de 2 á 5 años, por las siguientes enfermedades: Infecciosas á localizaciones variables, 1,797; infecciosas á localizaciones típicas, 1,153; aparato respiratorio, 885; enfermedades del sistema nervioso, 729;

aparate digestivo, 432; enfermedades génito-urinarias, 92; enfermedades de la nutrición, 62; aparato circulatorio, 23; enfermedades de la sangre, 10; enfermedades de la piel, 6; sin clasificación, 195; total, 5,384.

En los últimos años nuestra mortalidad infantil de 0 á 1 año ha oscilado entre 24 y 28 por ciento de la general. Comparemos los datos que á este respecto ofrece Paris, según Landouzy y Napias, y veremos lo siguiente:

| Años.     | Mortali-<br>dad total. | Mortali-<br>dad infan-<br>til de 1 día<br>á 1 año. | Mortali-<br>dad infan-<br>til de 1 año<br>á 2 años. |
|-----------|------------------------|----------------------------------------------------|-----------------------------------------------------|
| 1881..... | * 57,066               | 10,180                                             | 3,415                                               |
| 1882..... | 58,702                 | 10,541                                             | 3,320                                               |
| 1883..... | 56,707                 | 10,282                                             | 3,555                                               |
| 1884..... | 56,970                 | 9,970                                              | 3,803                                               |
| 1885..... | 54,616                 | 8,897                                              | 3,367                                               |

Así pues la mortalidad en los niños de 0 á 2 años en la capital de Francia, varia entre 23 y 25 por ciento de la total.

Los nacido-muertos en Buenos Aires han llegado á ofrecer muy lúgubre estadística, pues no solo interviene en ello el accidente natural de la muerte, sino que muy frecuentemente esta es el resultado del crimen.

Las casas particulares de partos, que hasta hace muy poco escapaban á la vigilancia de la asistencia pública, han sido en muchos casos los principales contribuyentes de esta entidad que la moral, la buena policía y la conveniente inspección harán disminuir. Otro factor que obra poderosamente para aumentar esta cifra es la ilegitimidad y con esta la miseria. El cuadro que sigue revela la proporción que los nacido-muertos representan en 100 defunciones generales en Buenos Aires:

| Año.      | Nacimien-<br>tos gene-<br>rales. | Nacido-<br>muertos. | Propor-<br>ción de na-<br>cido-muer-<br>tos con los<br>nacido-<br>muertos<br>generales<br>por 1,000. | Mortali-<br>dad<br>general. | Propor-<br>ción de na-<br>cido-muer-<br>tos sobre<br>100 defun-<br>ciones<br>generales. |

París y Buenos Aires ocupan los primeros lugares en esta estadística de mortinatalidad.

Buenos Aires, junio, 1893

#### METHODS EMPLOYED FOR THE PREVENTION OF DISEASE AND PRESERVATION OF THE LIVES OF THE INHABITANTS OF THE DISTRICT OF COLUMBIA.

By CHARLES M. HAMMETT, M. D.,

*Health Officer of the District of Columbia.*

I have the honor to appear among you as health officer of the District of Columbia, delegated to this congress by the honorable Commissioners, and I will proceed to state in as few words as possible the methods employed by the health department for the prevention of disease and preservation of the lives of its inhabitants. The ordinances of the health department, covering nearly all nuisances likely to occur injurious to health, were legalized by Congress and approved by the President on April 24, 1880, and we are now acting under these laws. The important features that may be spoken of are the system adopted for the issuance of permits for burial; the obtainance of information concerning births and marriages for statistical and other purposes; the method of inspections, especially that pursued during the present summer, of house-to-house visitations; the collection of garbage; the service of surveillance of houses infected with smallpox, scarlet fever, diphtheria, and other contagious diseases; the pound service; and the inspection of vessels arriving from foreign ports. The domiciliary inspection service was originated with a view to ascertain the sanitary condition of each and every house and premises within the District lines. It has been successful beyond my utmost expectations. During the period from March 17 last to the present time there have been 39,330 houses inspected. In these houses there resided 39,627 families, consisting of 190,718 adults, children, and infants. The number of rooms for their accommodation was 274,133. Closets and privies numbered 55,942. The water supply from the reservoirs from the Potomac River is 18,244; from hydrants in the public streets, 3,055; from wells, 4,619; cisterns, 69, and springs, 315. Over 13,000 nuisances of a minor character were found, which have been abated. This work has been done with an average force of twenty men.

The deaths for the following months, this and last year, were as follows:

|             | 1892. | 1893. |
|-------------|-------|-------|
| April ..... | 446   | 482   |
| May .....   | 434   | 473   |
| June .....  | 584   | 596   |
| July .....  | 835   | 609   |
| Total ..... | 2,299 | 2,160 |

Figures such as these, showing a gradual decrease in the number of deaths as compared with the increase in the population with the great finality of 196 less deaths during the month of July this year than last, is a most important evidence that house-to-house inspections, vigorously and faithfully carried out, as have been done here, with a competent force of inspectors, is one of the vital agencies to be employed. This, I consider, is one of the methods described so aptly by Dr. Mapother in his treatise on sanitary science for the maintenance of the health and life of communities by agencies in "common and constant use." The principles of physiology, pathology, and biology may be well carried out in this direction, supporting the cardinal idea of cleanliness. There are other agencies employed for the protection of the health of the inhabitants of the District of Columbia relating to sewers, drains, disposal of garbage and dead animals, disposal of the dead, etc., which may be spoken of as follows: Seventy-two thousand one hundred and thirty-eight healthy and vigorous trees are now growing upon the street lines of this city, and it is my belief that these trees have an important share in the healthful conditions surrounding us. We also have a free public bathing beach, which is used to the fullest extent whenever the weather will permit. More than 300 miles of underground sewers have been laid in the District of Columbia, at an approximate cost of \$6,800,000. These afford ample drainage for our present needs and have much to do with our good sanitary condition. The work is still progressing and large appropriations have been made for its continuance. Since the commencement of the large system of improvements 3,500,000 square yards of various pavements have been laid and the appearance of our streets and alleys always strikes the eye of the observing visitor with surprise, the miles upon miles of smooth pavement affording excellent drainage toward the sewer openings. Most of the streets are kept scrupulously clean, and filth upon any street or alley is the exception rather than the rule. The condition of our public school buildings is also about all that could be desired in such structures, the closest attention being paid to ventilation, heat, closets, etc. They are inspected frequently and anything in the shape of unsanitary matters is speedily abated. As a consequence, the breaking out of epidemics or the spread of diseases through the agency of the public schools is nearly impossible.

Relative to the vital statistics of the District of Columbia, will say that to the casual observer deaths, as they occur in a community, seem to present no order nor law in regard to age, sex, or social condition. Individuals seem to fall as the leaves of autumn fall. Old and young, in the alley or on the boulevard, in the tenement house or Executive Mansion, pass away one by one. But when the death certificates are arranged and classified, either according to age or cause of death, it will be seen that chance plays no part in this drama, and that fixed and unchangeable laws govern the whole matter of life and death. Statistics post the account and strike the balance. They disclose how age and social relation, and even meteorological conditions, influence the rate of mortality. They point out the advent and growth of strange maladies and novel phases of old ones; how some seem refractory and incurable, whilst others may be met and overcome. They designate where certain diseases linger for years around certain localities, and how the taint of blood may sap the fountains of life down through successive generations. In short, they furnish data from which science may deduce conclusions as wonderful as that by which Jenner enabled mankind to successfully fight smallpox, or as grand as that of Pasteur or Koch which taught how disease may be made to abort disease. It is upon the principle that statistics are valuable only when used as means of comparison that the tables contained in the annual report of this department are mostly arranged. They contain, in addition to the results of the immediate year, serial tables covering groups of years, arranged conveniently for reference. Besides these tabular statements, but deduced therefrom,

are annually drawn up three maps of the city, upon which are noted the number of deaths by race that have occurred upon each square. There also may be found the exact square upon which deaths from consumption, typhoid fever, malarial fevers, diphtheria, scarlet fever, and diarrhoeal diseases occurred. These charts are of great interest in showing the topography of mortality in the city, and are so highly esteemed by health officers in other cities of this country and in some European cities that they are being adopted as models from which to copy. The question would naturally arise as to whether these statements and arrangements of facts and figures show that progress has been made in limiting the death rate in this District, and has the average of human life been extended? By an examination of the tables it will be seen that the annual death rate has been gradually diminishing since the organization of this department. Commencing in 1876 with a rate of 26.4 per 1,000 inhabitants, and then falling in subsequent years to 25 and to 24, the report for the fiscal year ended on June 30 last shows a rate of but 22.6, a gain of 1,000 lives per annum. Proceeding further into particular classes, we find that the zymotic diseases present an almost corresponding improvement. Taking the last five years, the percentage of deaths from this class of maladies to the total mortality has declined from 24.2 in 1888-'89 to 20.5 in 1892-'93. As compared with the fiscal year 1892, there is an improvement of 1 per cent in 1893, and that condition, judging from subsequent reports, would seem to be continuous as to the immediate future. Mortality from typhoid fever, which has been as high as 208 in the year for two successive years, has decreased to 187 during the last year and to 183 in the preceding year. In the zymotic class diphtheria holds a prominent place as to frequency of attack and number of the victims and its fatal character. Until within two years there was no law by which the number of cases of this disease, and the location thereof, as well as deaths therefrom, in the District of Columbia, could be ascertained. During the year before last the number of cases occurring in the District amounted to 533, with 177 deaths therefrom. This was at a rate of mortality of 32 per cent of cases, or one patient out of every three dying. During the last fiscal year, under the operation of the same excellent law, the number of cases was 377, with 128 deaths, showing 49 reduction in the number of deaths and the large reduction of 156 in the number of cases. This result was attained by the rigid application of the law of isolation, which protects the public schools, the Sabbath congregation, all public assemblages, and the neighborhood from this deadly contagion. The scarlet-fever service comes under the same regulations as does diphtheria. In 1892 there were 385 cases of this disease reported, with 25 deaths. In the year just ended there were 209 cases, resulting in 7 deaths. Here was a decrease of 175 in the number of cases and of 18 in the number of deaths. The laws and regulations in regard to these diseases provide for complete isolation of the patient, the placing of warning cards upon the premises where the case exists, and the burning and disinfection of all material likely to have become a nidus for the germs. In this same class are included all those maladies embraced in the general term "miasmatic." In former years the malarial atmosphere of Washington afforded a fruitful theme for newspaper correspondents, and many excuses for physical conditions brought on by excess in living. Of late there has been a continued decrease in the number of so-called "malarial fevers" in fatal form. For the decade ending within five years ago the deaths from this class of diseases averaged annually from 110 to 112. Last year they amounted to 90, and in the year previous there were but 85. Say within the last five years the deaths from zymotic disorders have fallen from 24 per cent of the total mortality to 20 per cent.

Passing from the zymotic to the tubercular maladies, consumption demands most attention. Up to the great discovery of Dr. Koch as to the possible successful treatment of tuberculosis, the belief that pulmonary tuberculosis or pulmonary

phthisis might be arrested in its primary stages, or even in the more advanced conditions, had few if any advocates. But latterly the idea seems to have been gaining ground that this dread malady, even if hereditary in its origin, may be aborted or counteracted, if not cured, after having made serious invasion of the system. That pleasant and airy surroundings and good sanitation are influences which overcome a tendency to consumption may no longer be wholly controverted in view of the statistics of this city. The measures resorted to to clean up the place and its present sanitary condition have already been spoken of. In former years the deaths from consumption in this District averaged near 750 per annum. In the year 1884 they reached their highest mark, when they numbered 819. During the year 1892 there were but 714 deaths from consumption, while last fiscal year the number fell to 681, which is the lowest point since 1876, seventeen years ago, when they amounted to 579 out of a population of a little over one-half that now in the District. In this city the deaths from tubercular diseases have declined from 18.1 per cent of total mortality to 15.9 since 1889.

An unavoidable limit having been placed upon the extent of human life, the death rate can not by human agency be brought down to zero. While the foregoing statements go to show that certain diseases may be engendered and propagated by man's disregard of the law of life, there are others which seem to be inherited to humanity. These last will always claim their own. Among these are the nervous disorders, which cause annually in this city, with but little variation from year to year, 13 per cent of the total mortality. In the same class, diseases of the circulatory organs remain in fatal form at an even rate during the five years past, varying scarcely in that time from 5 per cent of total deaths. Since the advent of the catarrhal influenza in 1889-'90 the mortality from diseases of the respiratory organs has been greater than in former years. Previous to the year named the deaths averaged about 500 per annum, after which time they increased to 904 in 1891 and to 956 in 1892, and then declined to 905 in the fiscal year ended in June last, or 14 per cent of the total mortality, with indications of their return to original figures. The digestive organs were subject to the same influences. On an average in times past they have claimed 7 per cent of all deaths. In the past year they increased to 8 per cent, and from 444 in 1892 they rose to 525 in 1893. This increase was mainly attributable to cases of gastritis, gastric and gastro-intestinal catarrh, and enteric catarrh, many of which were no doubt super-induced by the expiring influence of the epidemic catarrh.

Among the innumerable new subjects now engaging the attention of the medical world infantile mortality is prominent. "Pediatrics" is the term applied to this branch of science. In this city no subject presents a more fruitful and useful line of research. Over one-third of all deaths in this District are of children under 5 years of age, and of these two-thirds are infants under 1 year old. During the year ended on June 30 last 2,361 children under 5 years and 1,770 under 1 year of age died. What may be the cause or causes and what the remedies for such conditions rest with the scientist and humanitarian. These are the facts as presented by the current reports

---

LA EMBRIAGUEZ, SUS CAUSAS, SUS EFECTOS, URGENTE NECESIDAD DE DISMINUIRLA, ¿CUALES SERÍAN LOS MEDIOS MÁS ADECUADOS PARA OBTENERLO?

Por el Dr. SALVADOR GARCIADIEGO, México.

Este vicio deplorable que carcome á la sociedad y cuyo incremento la hará sentir cada vez sus terribles consecuencias, merece llamar la atención de los higienistas para ver si es posible detener sus avances y salvar á la humanidad de los males sin número que le acarrea.

El utilitarismo, el materialismo, el positivismo y los demás dictados con que se engalana el epicureismo moderno para disfrazar sus tendencias en medio de la algazara y del entusiasmo frenético que desarrollan en las masas los adelantos actuales para hacerlas creer que el lema de la escuela enciclopédica, "Gozar de la vida y de sus placeres sin ocuparse de un porvenir desconocido," es el fin á que deben aspirar y el que señala su destino sobre la tierra, nos ha conducido al borde del precipicio.

Desde que por una aberración inconcebible se han limitado los deberes y derechos sociales á disfrutar las comodidades y ventajas con que nos brinda el progreso material, sin reconocer más tasa que el perjuicio notorio de tercero y se profesa que la sociedad está fundada en la aglomeración de individuos que por un pacto tácito ó expreso han resuelto vivir en común para obtener los beneficios que trae consigo la reunión de elementos aislados, y que cada uno de estos debe prestar contingente al desarrollo y perfectibilidad indefinida á que está llamada la humanidad, se han erigido principios absolutamente erróneos como base de la sociedad, de cuya aplicación han surgido necesariamente el imperio de la fuerza, el valor del oro y la abolición de los deberes hacia Dios. Olvidando que la sociedad es un compuesto que debe tener de la misma manera que los tienen las partes que la forman, deberes marcados por una ley superior á las que emanan de las conveniencias materiales y cuya observancia es impuesta por el capricho humano y sancionada con una penalidad no relativa á los crímenes, sino atenuada en proporción de su frecuencia, y finalmente llevadas á efecto por la fuerza armada, no debemos extrañar que todos aquellos vicios que dañan en primer término á los individuos que se entregan á ellos, se hayan multiplicado hasta el grado que la sociedad resienta ya sus funestas consecuencias.

Bajo este punto de vista deben estudiarse las causas y efectos de la embriaguez, si se pretende disminuirla, supuesto que los medios empleados con ese objeto, hasta la fecha no han sido coronados con buen éxito. Parece que el desarrollo del progreso material en la sociedad ha venido á entorpecer sus adelantos en el orden moral, fenómeno que no debe extrañarnos supuesto que lo mismo acontece en el individuo considerado aisladamente, y la colectividad tendrá que perfeccionar, que desarrollar si se quiere, atributos que pudieran pasar casi desapercibidos en él; pero nunca será capaz de abolir las leyes naturales que lo rigen en su evolución normal.

Salvo excepciones, que por el solo hecho de serlo jamás constituirán una regla general, el desarrollo excesivo de las facultades motrices, de los sistemas y aparatos orgánicos que ponen en juego y de las afectivas retarda y aún suele amenguar la evolución de las mentales y vice-versa. Esta ley fisiológica, cuya verdad está al alcance de todos, ha servido de norma á los higienistas para recomendar encarecidamente que en la educación de los niños y jóvenes se procure con empeño que haya paralelismo y simultaneidad en el desarrollo de unas y otras.

Inculcar á la niñez los deberes del hombre hácia el Ser Supremo, para consigo y respecto de la sociedad, fijando en su memoria los desastrosos efectos de los vicios por medio de anécdotas é historietitas que impresionan vivamente en esta tierna edad, representándole en toda su desnudez y repugnancia la degradación á que conduce la embriaguez y que es el semillero de los vicios y desgracias que minan nuestra sociedad actual, para que los niños le cobren horror desde sus primeros años. Seguir un plan análogo para la educación de la juventud y ser inexorables los directores de los colegios de instrucción secundaria con los alumnos que desgraciadamente se inclinan á dicho vicio, y continuar el mismo método y una disciplina severa en los colegios profesionales. Este medio dará excelentes resultados para el porvenir, siempre que se tenga especial cuidado de premiar, á la par que los adelantos científicos y aún con preferencia, la buena conducta de los alumnos.

Respecto del presente, no siendo posible educar hombres, sí lo es corregirlos, y la manera más adecuada es servirse de la penalidad impuesta á la embriaguez. Debe tenerse presente que el que se expone voluntariamente á perder su razón y á entregarse á excesos cuya trascendencia ni él mismo puede medir, es doblemente culpable, primero, por la falta que comete privándose de su razón, y segundo, por los actos que en tal estado puede ejecutar y ejecuta de ordinario cuando se embriaga, circunstancia agravante y que debe tenerse en cuenta por el legislador, pues sabido es que individuos pacíficos se tornan pendencieros y aún asesinos con los vapores del vino. Que la legislación jamás atenúe el delito cometido por un ebrio de oficio ni del que voluntariamente y á sabiendas de los efectos del alcohol sobre el cerebro se exceda en la bebida, que la penalidad impuesta á los crímenes perpetrados por individuos en estado de embriaguez, sea mayor y efectiva, y puede asegurarse sin temor de engaño, que el número de consuetudinarios disminuirá. Habrá necesidad de algunos ejemplares, quizás podrá tacharse de severa esta manera de proceder, pero el resultado práctico vendrá á hacerle justicia, y las ventajas serán reportadas por la sociedad. Si la legislación moderna es tan indulgente con los criminales, buscando razones para excusar hasta cierto grado los delitos á la sombra de la perversión de instintos, de la degeneración moral de ciertos individuos, del estado en que los coloca la embriaguez, la consecuencia forzosa es que la sociedad está desarmada delante de los agresores de sus intereses, so pretexto de no condenar al reo que en el acto mismo de perpetrar el crimen no disfruta del pleno uso de su razón.

Cuando á los degenerados, epilépticos, locos de impulsión, etc., se les vigila y se les segrega de la comunidad para sustraerla de sus tiros, causa pena y extrañeza que no se proceda de igual manera con los ebrios de profesión. Todavía tratándose de estos últimos, tendría que ventilarse la cuestión de si tienen conciencia del acto criminal que ejecutan y el vino solamente los priva del temor natural de ejecutarlo por las penas con que se castiga un hecho de este género en un cuerdo, circunstancia que aumenta su audacia con la perspectiva de la inmunidad relativa, ó si realmente deben calificarse como privados de razón.

La importancia del asunto demanda algunas consideraciones médico-legales sobre los efectos del vino en las facultades que constituyen la razón humana, y la apreciación que han hecho de ellos algunas legislaciones vigentes en la actualidad. Después de este estudio sucinto, sería del mayor interés para nuestras legislaciones y para la sociedad, que se fijaran reglas de conducta para el juez y el perito, á fin de poder determinar con precisión cuales de los actos cometidos en estado de embriaguez podían estimarse concientes, y cuales voluntarios en la causa, y por tal motivo siempre imputables.

Los códigos de Austria, Prusia y Baviera dicen que ningún acto puede ser reputado criminal cuando su autor se encuentre en estado de ebriedad completa y accidental.

En Inglaterra, según Blackstone, la legislación criminal afirma que la falta de voluntad en el ebrio en el momento del crimen, lejos de servir de excusa, agravará el delito porque debía no embriagarse y ser dueño de sí mismo. Eduardo Coke ha dicho: "Un ebrio es un demonio voluntario que es responsable de los males que pueda causar durante la vehemencia del vino." La legislación norteamericana es análoga. La ley de Georgia, sin admitir como excusa la embriaguez, exceptúa el caso de haber sido ocasionada por artificios de un tercero. El código de Wurtemberg establece una distinción entre el ebrio y el consuetudinario; teniendo indulgencia con aquel y siendo muy severo con este, para castigar el delito y el vicio. En general se cree que la frecuencia de actos criminales de tal ó cual género debe suavizar la penalidad de los códigos respecto de ellos; mas es muy importante tener presente la rigidez de la legislación inglesa que contraria

esta regla, pues es tan común en dicho país la embriaguez, que asegura Taylor, que si la estimasen como excusa las tres cuartas partes de los criminales quedarían impunes.

La embriaguez presenta tres períodos según Hoffbauer: (1) Excitación ó exaltación de las facultades mentales y de la fuerza física, hilaridad, buen humor, alguna incoherencia en el lenguaje y frases indecentes, integridad de los sentidos y conciencia plena. (2) Depresión. La imaginación decrece y se extingue, la voz se eleva y aparece la turbulencia, la circulación cerebral es más activa, la respiración se acelera, los sentidos se debilitan, y al fin se embotan, los movimientos son inciertos, la pronunciación torpe, los miembros vacilan, la incoherencia del lenguaje muy manifiesta, la memoria y la voluntad desaparecen, las pasiones se encienden y estallan con el más ligero pretexto produciendo arranques irresistibles, favorecidos por las frecuentes alucinaciones é ilusiones que acompañan este estado. El hombre en tal situación se asemeja mucho al maniaco, y es tan peligroso para los demás como para sí mismo. (3) Coma. Un sueño profundo, apoplético, caracteriza el último período de la ebriedad, el individuo sumergido en él, extraño á los objetos que le rodean, inofensivo para la sociedad, aparece como una bestia que resiste al frío y al contagio, como lo ha establecido Double, por que ha perdido los caracteres propios del hombre y se ha colocado en una escala inferior. Existe además otra forma de embriaguez: la convulsiva. Al describirla Percy y Laurent se expresan en estos términos:

Diez hombres pueden apenas dominar á esta especie de fieras. La mirada es feroz, los ojos centellantes, los cabellos erizados, los gestos de amenaza, rechinan los dientes, escupen la cara de los circunstantes, muerden á los que se les aproximan, les hincan las uñas si tienen las manos libres, escarban la tierra y prorumpen en ahullidos espantosos. Si por desgracia están á solas, pueden arrojar por la ventana, herirse, rodándose por el pavimento ó estrellarse la cabeza contra las paredes ó la cama. Hemos visto perecer dos desgraciados de esta manera.

La duración de la embriaguez es muy variable y guarda proporción con la aptitud individual, la naturaleza y cantidad de las bebidas espirituosas, la composición de las falsificadas, la costumbre de embriagarse, etc., de suerte que es muy difícil determinarla, á pesar de ser importantísima esta circunstancia para el juicio pericial, porque el juez necesita saber si en el momento de la perpetración del delito se encontraba su autor en el segundo período de la ebriedad, que sería el que pudiera excusar parcialmente la responsabilidad de un acto, por hallarse disminuida la inteligencia y exaltados los sentimientos afectivos; que los cometidos en el primer período ó después que el segundo había terminado, deberían ser imputables, porque en uno no se pierde aún el uso pleno de la conciencia y después del otro la razón recobra sus derechos. Omitimos ocuparnos del tercero, porque es imposible ejecutar actos violentos en él; el individuo se ha convertido en cosa y la personalidad ha desaparecido.

Respecto de la embriaguez convulsiva, del período de delirium tremens y del estado de embrutecimiento moral y físico en que suelen caer los consuetudinarios, el primero se relaciona con los accesos furiosos del maniaco, el segundo con los actos inconcientes de un enfermo delirante y el tercero constituye un estado particular que merece nuestra atención. Bajo el punto de vista médico-legal el abuso de la bebida, si no viene acompañado de delirio, confirmado y permanente, no debe aumentar ni disminuir las consecuencias del acto cometido, solamente debilitará ó disipará la sospecha de la embriaguez intencional con fines culpables; tal es el sentir del distinguido alienista Legrand de Saule, que al ocuparse de la materia añade:

No puede concebirse que el hábito de la embriaguez alcance de los magistrados graciosa deferencia, cuando su misión los llama á perseguir el escándalo y condenar la inmoralidad.

La embriaguez periódica ó intermitente dimana de la perversión, la sensualidad, la imitación y la disolución de costumbres. (Marc.)

La acción de la justicia contra ella es soberana y su fallo dependerá de la apreciación discreta de la moralidad del hecho. (Legrand de Saule.)

La historia de las desgracias ocasionadas por la embriaguez es un largo y sombrío martirologio. (Dumesnil de Quatre-Mares.) Cinco siglos atrás, en 1349, á propósito de este asunto el prefecto municipal de Rouen dijo: De veinte bandidos ó salteadores, diez y nueve se han formado en las tabernas.

Licurgo embriagaba á los ilotas para inspirar á los ciudadanos horror por la ebriedad. Aristóteles y Quintiliano afirmaban que agravaba al crimen y que debería castigarse con una pena independiente de la que aquel reclamaba, por ser una degradación voluntaria, la cual nunca podría ser medio de justificación ni crear una excusa.

Se mejoran la plantas con el cultivo y el hombre con la educación. (Rousseau.) En el día, la educación es prodigada con largueza y sin embargo el mal hace progresos. La sociedad exige que se dicten medidas repressivas; para tener buen éxito, preciso será herir el corazón. (Legrand de Saule.)

Los progresos deplorables del alcohol y sus efectos desastrosos conducen á los más eminentes pensadores, no solo á rehusar á la embriaguez el carácter de excusa legal (lo cual había ya proclamado la jurisprudencia del tribunal supremo tiempo ha, considerándola en sus sentencias como hecho voluntario y reprehensible que jamás podrá constituir una excusa capaz de ser acogida por la moral y por la ley), sí que también á reputarla circunstancia agravante del crimen y de la penalidad. La asamblea nacional en 1871 se ocupó de este punto, y entre los esfuerzos intentados en esta vía, los más enérgicos y mejor dirigidos fueron presentados por el Dr. Teófilo Roussel. (Tardieu.)

El código francés hace punto omiso del estado de embriaguez, dejando en libertad á los jueces para calificar la responsabilidad (Briand et Chaude), medida muy sabia que puede poner á salvo los intereses de la sociedad y los derechos del hombre, porque el magistrado falla á impulsos de su conciencia y no de la ley escrita. La historia, la legislación de países demasiado ilustrados, y la opinión de médicos-legistas, tan eruditos y prácticos como los que hemos citado, vienen en apoyo de la moral y de la filosofía para demostrar una vez más que el individuo que voluntariamente se coloca en condiciones que puedan arrastrarlo á cometer actos punibles concientes, semiconcientes ó inconcientes, es doblemente responsable por renunciar á la razón deliberadamente y obedecer á ciegas los instintos de sus malos hábitos; que los delitos cometidos bajo la influencia del alcohol deben ser castigados, y que la embriaguez no debe estimarse circunstancia atenuante, ni atenderse al desarrollo que ha alcanzado en nuestra época, porque siempre que los códigos suavicen la penalidad por tal consideración, lejos de corregirse, crecerá á sus anchas, contando con la impunidad relativa de ser castigados como faltas, sin calificarse de crímenes imputables los atentados perpetrados á su sombra.

Es bien lamentable que la trasgresión de las leyes del deber ejecutada por un hombre honrado en un momento de desgracia en olvido de sus deberes, sea castigado con la severidad impuesta por la legislación, al paso que delitos mucho más repugnantes, llevados á cabo por individuos que corrompen y vician las costumbres sociales, encuentren una egida que les sirva de amparo, trayendo á colación en su defensa y á título de excusa, un vicio que corroe á las sociedades modernas, y que echará más hondas raíces toda vez que la legislación lo tolere y aún lo proteja indirectamente, atenuando las penas con que se reprimen los actos punibles de sus adeptos.

Ya hemos referido la opinión de Taylor, en la cual se nota la confesión ingenua del estado deplorable que ofrece el pueblo inglés por su afición á la bebida, y que si fuera admitida la embriaguez como excusa legal ante el jurado, tres cuartas partes de los criminales gozarían de impunidad.

Que nos sirva de ejemplo esta lección para que jamás lleguemos á semejantes extremos; que nuestros legisladores fijen su atención sobre cuestión tan importante y opongan un dique á los avances de un vicio que después de destruir al

individuo, disolver la familia y perturbar el orden y decoro social, se perpetúa en la descendencia marcando sus huellas con lesiones cerebrales y faltas de desarrollo físico y moral; que declarén responsables de sus actos á los consuetudinarios, para que si no obtienen la desaparición de la intemperancia, hayan cumplido, por su parte, la alta misión que desempeñan, vigilando por el bienestar de la comunidad y reprimiendo los actos que la trastornan.

### PALUDISMO.

Por el Dr. ANTONIO JOSÉ AMADEO.

*Doctor en medicina de la Universidad de Pensilvania, M. R. C. S. E., etc.*

Prescindiremos del saneamiento de los campos, y lo que pertenece á la higiene pública, para ocuparnos de los medios de preservar al individuo. Son raras las fiebres palúdicas, siempre que haya buenas viviendas en sitios elevados, secos, alimentos suficientes y vestidos apropiados al clima (telas de algodón), evitando las fatigas corporales, las mojaduras, los excesos de todo género y los enfriamientos repentinos. Cuando existe una endo-epidemia, se deben tomar al acostarse seis ú ocho granos de sulfato de quinina cada dos ó tres días, manteniendo el vientre libre con el uso de naranjas dulces y algunas tomas de bicarbonato de soda.

Los agricultores no deben salir muy temprano sin desayunarse.

El café negro por la mañana y la cerveza con agua al medio día, cuando hay mucha sed sientan siempre bien. Lo mismo las fricciones alcohólico-aromáticas después de los enfriamiento repentinos y mojaduras. El sereno es uno de los peores enemigos, y las malas noches pasadas en bailes, orgías, viajando producen la intermitente. La constipación debe combatirse con ligeros laxantes.

### TRATAMIENTO.

Hay individuos que se curan las intermitentes sin tomar ningún medicamento, por la sola fuerza de la naturaleza; su privilegiada organización para eliminar de la economía sustancias tóxicas, ó tal vez como cree Mr. Laveran y sus secuaces, debido á la fagocitosis destruyendo los hematozoos de la malaria. Bastan para cortar una palúdica simple tomar quince granos de buen sulfato de quinina al terminar el acceso; ocho granos más al día siguiente, y doce granos siete días después, dos veces seguidos para evitar las recidivas. Contra los síntomas gastro-biliosos, un vomitivo de tartrato de potasa y antimonio, seguido de un purgante de calomelano. El arsénico y demás sucedaneos de las preparaciones químicas, no son tan eficaces contra las manifestaciones palúdicas. Las personas de diátesis artrítica tienen aquí calenturas accesionales (simulando el impaludismo), que resisten á la quinina y se combaten con el arsénico y las aguas minerales termales. (Baños de Coamo.)

En la remitente con síntomas biliosos; un vomitivo de tártaro emético; un purgante de calomelano, seguido de otros de aceite de ricino son remedios eficaces. Las prevenciones contra el antimonio carecen absolutamente de fundamento, considerándole siempre muy superior á la ipecacuana, que reservamos para las personas muy debilitadas. Hasta en los niños produce los mejores efectos. La antipirina después de abundantes sudores rebaja la temperatura y prepara el organismo para la administración pronta de los antiperiódicos por todas las vías. En toda pirexia remitente ó pseudo-continua, deben combatirse inmediatamente las congestiones locales; lo mismo que sostener la hipercrinia intestinal para eliminar sin demora de nuestra fábrica los productos nocivos ó tóxicos. Los infartos crónicos del bazo é hígado, requieren los revulsivos, el yoduro de potasa, y hasta el

mercurio, cuyo último medicamento según nuestras observaciones, en vez de empobrecer más la sangre, mejora sus condiciones y favorece la nutrición. Desde tiempo inmemorial se emplean aquí por el vulgo, para curar las intermitentes palúdicas, la quina caribœa el agenjo (*Partenium hysterophorus*), el quinino del pasto (*Phyllanthus nicuri*), la hedionda (*Cassia occidentalis*) el Condeamor (*Monordia charanta*) y otras plantas tónicas con la ayuda de purgantes drásticos.

La anemia se combate con los buenos alimentos, el cambio de lugar y las aguas minerales, sódicas y ferruginosas. El hierro, la mayor parte de las veces, produce constipación, perturba las funciones digestivas, y no da los resultados que se esperan. La hidroemia en los niños, no tiene tanta gravedad como en los adultos, y se cura con los vegigatorios al bazo, á la región hepática, purgantes drásticos, los tónicos, y cambio de residencia con una buen alimentación.

Varias son las hipótesis sobre la acción de la quinina, pero hasta hoy no se conoce bien su manera de obrar. Creese que triunfa de la intermitente destruyendo los hematozooarios de Laveran, mas ya hemos dicho que no siempre se encuentran estos micro-organismos en las fiebres palúdicas, siendo una teoría como otra cualquiera, hasta que no se haya dicho la última palabra sobre la naturaleza y fuerza infecciosa de estos raros parásitos. Lo que no debe ponerse en duda, es la acción pronta, fortificante de las sales de la quina sobre el sistema nervioso, por lo que creemos combaten las palúdicas, estando indicadas en todas las enfermedades de esta zona cuando hay intermitencia y periodicidad aunque sean independientes del impaludismo. Son un neurosténico poderoso, indispensable, sin igual, en la terapéutica de estos países. En los estados adinámicos no tienen rival.

## SECTION XIX—PHARMACOLOGY.

---

*Executive President,*

Prof. JOS. P. REMINGTON, Ph. M., F. C. S.

*Secretary,*

Prof. F. G. RYAN, Ph. G.

*Foreign Secretary.*

Prof. A. W. MILLER.

---

### ADDRESS OF THE PRESIDENT OF THE SECTION, PROF. JOS. P. REMINGTON, Ph. M., F. C. S.

GENTLEMEN : It becomes my duty, as executive president of the section of *materia medica* and pharmacology of this congress, to address you upon this occasion, and to lay before you the reasons which have actuated the executive committee in establishing this section. The Pan-American Medical Congress, the first to convene in America, has for its mission the establishment of closer relations between the members of the medical and allied professions of the Western Continent. When we consider the enormous advances which have been made in the last century in all matters pertaining to the development and advancement of the human race, it is remarkable that so many years have elapsed, and that so many opportunities for mutual assistance have been permitted to drift away, until they finally rest in that unfathomable abyss which is filled with lost opportunities and shattered hopes. The medical and scientific literature of this country, with its wealth of accumulated facts and valuable researches, and the practical results flowing from the labors of the eminent men who have enriched American medicine and pharmacy with services which have received recognition in nearly every country, have been utilized freely all over the world, and yet we meet here to-day in the closing years of the century and find that our brethren to the south are still drawing their supplies, still sending the results of their researches, and still looking to the old countries across the water for their inspiration and for their intellectual help. The establishment of closer relations between the members of the profession of the Western Continent will not bar the communication which has been so long established with the mother countries. There is ample room for more. The old truism still stands, "Knowledge begets knowledge," and there is no reason why North and South America should not join hands, drawing from each other what is best in each, and in turn gleaning from the older countries all that can be gathered; and, although constantly adding to the accumulated stock, forever reaching out and possessing the resources of each to the fullest extent. Fortunately, the bounds

for the acquisition of knowledge can not be selfishly limited by any nation. Opportunities for advancement are all but universal in application, and universities are established all over the world. A glance at those great storehouses of technical information, our dictionaries of chemistry and encyclopedias of pharmacological facts, will disclose the names of scientists from all countries attached to the various subjects. Of late years the universality of science has received a wonderful impetus through the marvelous development of electricity, which seems to be destined to annihilate space and to swallow up the difficulties which stand in the way of the universal communication of thought and work between man and man. The varied climate and soil of South America have produced in times past a multitude of plants having very marked characteristics, and while a number, like cinchona, coca, jaborandi, ipecac, and others which are well known, have found their way into commerce, there is little doubt that the unexplored fastnesses would reveal to the explorer a large number of valuable drugs with which to enrich our materia medica, while the possibilities of cultivating many which have already proven their value gives abundant hopes for the future. Commerce and civilization are to-day almost synonymous terms. If South America can furnish the crude products from her soil, North America stands ready, with her marvelous facilities for refining and manufacturing, to present to the world finished products fitted for the use of the physicians of both continents. Why should not the north and south join hands in friendly commercial intercourse? The barrier which looms up at once is this, the wide difference in the standards used for medical practice in the two countries. Until the present time the systems of weights and measures were unlike. The adoption of the metric system by the Pharmacopœia of the United States of America has effectually settled one great difficulty, but another remains. The preparations of the United States Pharmacopœia and the preparations used by the pharmacopœias of South America differ in important particulars, and while it can never be expected that a Pan-American pharmacopœia could take the place of the official standards of the different countries, because these are regulated by law, there would seem to be no real objection that can be urged against the gathering into a Pan-American pharmacopœia of such drugs and preparations as are used in both countries, establishing standards for identification and purity which will aid in bringing order out of chaos and establishing a basis upon which the practice of medicine made by the physicians and the dispensing of remedies by the pharmacist can be carried on with safety and success. It would probably not be wise to aim at first at the production of an elaborate work; only such remedies as have proved to possess value should receive recognition, and such remedies which are indigenous to North America should be incorporated. It would not be desirable to introduce any substance or preparation in such a pharmacopœia which was controlled by copyright, trade-mark, or any monopoly; but after prescribing tests for identity or purity, every step should be taken to make the manufacture or collection of the substance as free as possible, so that any citizen in either of the countries should have the free right to collect or manufacture, provided he furnishes honest products at fair prices. We are here to-day to discuss and possibly to take the first steps toward the realization of such a project, and the first problem which should be settled is the desirability of having a Pan-American pharmacopœia. Then how shall it be prepared? What shall be its scope? What language shall it be published in? How shall it be published? Who shall constitute the committee to perform the labor? These questions can all be satisfactorily answered at this congress, and upon this section will devolve the important duty of inaugurating the movement, if in its judgment it seems proper to do so. In conclusion, gentlemen, as your presiding officer, I must ask for your kind indulgence, trusting that our deliberations may prove of service to the great movement in which we hope to bear successfully such portion of the burden as is laid upon us.

## DISCUSSION.

A. W. MILLER. It is comparatively easy to prepare a pharmacopœia, but it is infinitely more troublesome to have the same adopted and generally accepted. We must not overlook the fact that our South and Central American friends are somewhat conservative, and that they are jealous of anything savoring of dictatorial interference in their home arrangements. I therefore feel strongly convinced that no pharmacopœia prepared solely by us will ever meet with general recognition in the countries to the south of us. In my private opinion, the only feasible plan for the preparation of a Pan-American pharmacopœia will be to follow out the idea outlined in the president's address, namely, to have official representatives appointed by each of the Governments of Central and South America, which gentlemen are to be intrusted with this important subject. I apprehend that this will be a labor of several years, that the amount of correspondence will be enormous, that mutual concessions will have to be made, but that all this procedure will be absolutely necessary so as to insure the uniform acceptance of the new standard as an official authority in all of North and South America.

Mr. F. B. KILMER, New Brunswick, N. J. As for the association, I represent the State of New Jersey, and I indorse the plan of a Pan-American pharmacopœia. A recent examination of some of the pharmaceutical preparations of South America, and conversation with pharmacists and physicians is convincing of the need of the same. The medical practice of South America is as progressive as that of other parts of the world, but for various reasons different and older standards than ours are favored. Pharmacy in this section does not fulfill all modern demands. A Pan-American pharmacopœia would probably have to be of a much wider scope than our own or even an international pharmacopœia. It would have to embrace many preparations similar to our national formulary. In fact, this formulary was recently commended and purchased for use by a pharmacist in these States. If this section can furnish the initiative and secure the coöperation of representatives of these countries we may be able to mutually aid pharmacy in all the nations by an interchange of pharmaceutical standards and methods.

---

PROCEEDINGS.

---

## FIRST SESSION.

WASHINGTON, D. C., *September 5, 1893.*

The section was opened by the executive president, Prof. Joseph P. Remington, at 3:30 p. m.

The president requested the secretary to read the call for the meeting of the section, after which the president read his address.

Dr. A. W. Miller moved that the address be received and a committee of two be appointed to consider the suggestions made therein.

Seconded and carried.

The president appointed Dr. Robert W. Greenleaf, chairman, and Dr. A. W. Miller, to report at the next session.

On motion of Dr. Miller the section adjourned.

## SECOND SESSION.

Called to order by the president at 3:30 p. m.

Minutes of the first session read and approved.

Dr. A. W. Miller moved that, as the President of the United States of America had appointed 5 p. m. as a time to receive the members of the congress, this section take a recess at 4:45, and resume business after the reception.

Seconded and carried.

Dr. Robert W. Greenleaf, chairman of committee on president's address, made report as follows:

The committee appointed to consider the address of the executive president respectfully report that they fully approve of the various suggestions contained therein for furthering fraternal relations between the American Republics. We regard with especial favor the proposal for a Pan-American Pharmacopœia, particularly since listening to the remarks in the discussion which were brought out by the reading of the address. We feel very strongly convinced that the earlier this highly important matter is undertaken the better it will be for all the nations of North and South America. We therefore recommend that this subject be taken up for further deliberation at our next meeting.

Report received and adopted.

Dr. H. H. Rusby, New York, reported that the section on therapeutics had passed a resolution, as follows:

## PROJECT FOR THE FORMATION OF A PAN-AMERICAN PHARMACOPŒIA

The advantages which the pharmaceutical and medical professions derive from the uniformity of medical formulæ are well known, and this has led to the formation of pharmaceutical codes. The amount of drugs and preparations of American origin are already so numerous that it becomes necessary to embody them all in a work that will afford to the medical profession a ready means of consulting a therapeutic guide for their daily practice, the work being an exponent of the resources that our continent, so rich in natural productions, affords. The compilation of that pharmacopœia can be intrusted to medical professors of all the countries on the American continent, who would hold the character of collaborators, continually forwarding their contributions to the editorial center located in some one of the American nations. In furtherance of this object, and without hesitation, we offer with the utmost sincerity the National Medical Institute of Mexico, where for years past our scientific labors have been carried on with the view of acquiring all the necessary data for the pharmacological and therapeutical study of our national products. It is well known that our establishment contains departments devoted to the study of natural history, chemistry, experimental physiology, therapeutics, climatological and medical geography, and clinics, and that, therefore, it has at its disposal the best elements for those classes of studies. Should this project be realized, one of the great advantages to be derived from it will be that of placing in personal contact all the members of the medical profession throughout America and their interchange of information with regard to the resources which therapeutics can rely on throughout the continent will be an efficacious aid in fulfilling the duties of our profession. To insist on setting forth the importance of this plan would be an offense to the enlightened and learned body of my honorable colleagues, and I therefore submit to their consideration the following propositions: (1) All the nations of America will adopt a uniform pharmacopœia which will be denominated the Pan-American Pharmacopœia; (2) a committee of physicians and pharmaceutical chemists of all the American countries will be appointed, said committee to be intrusted with the formation of the above-mentioned work, compiling for this purpose all the pharmacopœias of America, and increasing it with the data that they may acquire; (3) this congress will appoint the central commission as also correspondent members resident in all the countries of America and will also fix the residence of the central committee.

This resolution was proposed by Dr. Rusby and seconded by Dr. Cerna in the section on therapeutics, and carried.

The following resolution was offered by Prof. Joseph P. Remington:

Whereas the section on pharmacology of the Pan-American Medical Congress, believing that there are many drugs, plants, and vegetable substances belonging to the South American flora which can be profitably added to our materia medica whose properties have never been investigated, and with the object of aiding in the development of these valuable resources of the Western Hemisphere: Be it therefore

*Resolved*, That this section recommend to the executive committee of this congress the organization of a Pan-American commission, whose duty it shall be to encourage the discovery of such drugs and provide for a thorough and exhaustive examination of the physical, chemical, and therapeutical properties of the same through the use of the best means known to modern scientific research.

Adopted.

The following resolutions were offered by Dr. H. H. Rusby:

*Resolved*, That this section recommends that steps be taken toward the preparation of a Pan-American pharmacopœia.

*Resolved*, That a committee of three be appointed by the chair, and that the section on therapeutics be requested to appoint a similar committee, the two committees to act jointly in formulating a general plan for carrying out the above idea; this plan to be presented, with recommendations by the two sections, to the executive board of this congress.

Mr. Burroughs moved its adoption.

Carried.

Resolution by Dr. H. H. Rusby:

Whereas the health of the community is a consideration of the highest import to the commonwealth, and the means for the prevention and cure of sickness should be brought without impediment within the reach of all members of the community; and

Whereas any artificial increase in the cost of antiseptic substances, drugs, mineral waters, and pharmacological preparations of known and stated composition tends directly to interpose such impediments to their use; and

Whereas the present tax upon medicaments and pharmaceutical substances constitute such an increase which weighs especially hard upon those whose wage-earning power is, by disablement, impaired and diminished, and inasmuch as artificial enhancement of cost is especially injurious to the sick poor, acts as a tax on the charitable funds of hospitals, and drives many to dispensaries and other public charitable institutions who would otherwise be enabled to supply themselves with the necessary medicine: From these and other considerations it is hereby

*Resolved by this pharmacological section of the Pan-American Medical Congress*, That it is inexpedient and contrary to public policy and injurious to the best interests of the community, and especially of the industrial classes and of the sick poor, that any tax or duty should be levied upon drugs and pharmaceutical preparations of known and stated composition; and that Congress is hereby earnestly and respectfully prayed to remove and remit all such existing taxes and duties, so that the means of preserving health and of averting and curing sickness may be placed at the disposal of the people without any artificial enhancement of cost.

Moved to adopt. Seconded and carried.

The section called to order after a recess of half an hour.

The president appointed Dr. H. H. Rusby and Dr. Adolph Miller a committee on Pan-American pharmacopœia, to act with a similar committee representing the therapeutic section.

Adjourned.

---

## MATERIA MÉDICA Y FORMULARIO MÉDICO DE VENEZUELA.

Por el Dr. ENRIQUE MEIER FLEGEL,

*Secretario de la Sección de Materia Médica y Farmacología del Congreso Médico Pan-Americano.*

Úsanse en Venezuela, con preferencia, las sustancias medicamentosas sancionadas por los estudios y experiencias de los laboratorios y clínicas europeas y americanas, ciñéndose para su aplicación á las prescripciones del Códex y de las farmacopeas británica y americana principalmente, modificando cada médico las

fórmulas según las necesidades de la clínica, como se verá en las fórmulas que van al fin de este estudio. Las sustancias de origen vegetal propias del país, usadas científicamente son pocas, á pesar de haber muchas de un uso popular extenso, y que no creemos desprovistas de propiedades; pero que necesitan el estudio fisiológico y la experimentación terapéutica. La mayor parte de los datos aquí recopilados, que se relacionan con nuestra flora propia, los hemos tomado de la materia médica de Benítez y el médico botánico criollo de Grousurdí. El Dr. J. A. Rísquez, que en su continuo anhelo de saber é investigar, había emprendido ya este trabajo, nos suministró gran parte del material, y nuestros maestros, los Dres. Elias Rodríguez, Nicanor Guardia, J. M. de los Rios y Calixto González, eminentes profesores que nada tienen que envidiar á las notabilidades extranjeras, nos han ayudado con las luces de su propia experiencia y las fórmulas que una larga práctica ha sancionado.

Para todas nuestras más expresivas gracias por su valioso contingente.

#### PLANTAS DE VENEZUELA USADAS POR LOS MÉDICOS DEL PAÍS.

(1) *Albahaca* (*Ocimum bacilicum*, *Labiadas*).—Planta tropical que crece con abundancia entre nosotros; sus hojas tienen un sabor fuerte, picante y agradable. Se usa en cataplasmas como resolutive; aplicada sobre la frente hace arrojar los gusanos de la nariz y de los senos frontales. El zumo de la planta se usa como diurético. Se asegura que algunas gotas instiladas en los ojos devuelven á la córnea su transparencia. Mezclada con mirra se aplica al tratamiento de la ciática. Contiene mucho alcanfor y el Dr. Bodard la propone como sucedánea de él.

(2) *Aguacate* (*Persea gratissima*, *Lauras persea*, *Lauráceas*).—Árbol de hermoso follaje, con hojas ovales y gruesas, flores arracimadas y amarillentas, fruto de color verde y colgando de grandes pedúnculos. De la fruta se saca un aceite fijo, amarillo verdoso, algo acre y que contiene laurina; las semillas contienen gran cantidad de tanina, y se aplican machacadas en forma de cataplasmas en los panadizos para abortarlos; tostadas y pulverizadas, finalmente, se usan para el tratamiento de las diarreas y disenterías; este mismo polvo mezclado con aceite se aplica con resultado para el tratamiento del hidrocele incipiente. El cocimiento de las hojas se usa para el tratamiento de la bronquitis crónica, y se asegura que la corteza es útil en las fiebres intermitentes.

(3) *Algodón* (*Gossypium canadensis*, *Malváceas*).—Además de los usos conocidos en cirugía, recomiéndase el zumo de las hojas como anexosmótico para los niños y analgésico para los dolores de oído; las hojas para el reumatismo crónico y carbunclos, aplicadas localmente; la cajilla del fruto, majada y tierna, destruye los clavos de la buba; el aceite de la semilla se emplea en la tos.

(4) *Algarrobo* (*Himenea curbaril*).—Contiene una sustancia resinosa que brota por las contusiones hechas en el tronco y en la raíz, la cual se usa en fumigaciones para el tratamiento del asma. Con la resina se prepara un bálsamo que se usa en los dolores reumáticos y en las ulceraciones de mal carácter. La corteza del árbol es á la vez purgante y carminativa, y se usa también como vermífugo. Contiene una semilla farinácea que puesta en maceración con aguardiente da una bebida agradable y algo purgante, perdiendo con el tiempo esta última propiedad. Algunos creen que la resina del algarrobo es el bdellium de los antiguos.

(5) *Algalius* (*Abel moschus moschatus*).—Las semillas de esta planta tienen olor á almizcle muy pronunciado y contienen un aceite fijo, mucílago, una sustancia albuminosa y una resina. En Guayana se usa como antiespasmódico para el tratamiento del tétano. Se conoce también con el nombre de almizcle vegetal, y se usa como sucedáneo del almizcle de Tonquín.

(6) *Amapola* (*Plumieria alba*).—La infusión de las hojas de esta planta tiene virtudes pectorales, y se usa en la bronquitis para calmar la tos, y especialmente en la toserina.

(7) *Borrajon* (*Heliotropium indicum*).—Planta como de media vara de alto, de la cual se usa la cataplasma de las hojas como resolutive y la infusión como sudorífica.

(8) *Brusca* (*Cassia occidentalis*, *leguminosas*).—Planta de media á una vara de alto. Se usa como antiespasmódico, febrífugo y emenagogo. El cocimiento se aplica en la dismenorrea, cólicos uterinos, supresión de los loquios y el reumatismo.

(9) *Bejuco de cadena* (*Schenella splendens*).—Se usa como sudorífico y anti-blemorrágico. Entra en la preparación de casi todos los jarabes depurativos que se preparan aquí.

(10) *Calaguala* (*Planta cryptógama*, *Polypodium crasifolium*).—Se utiliza la raíz, que es cilindroidea, bermeja, cubierta de fibras largas en cocimiento, como diurética y sudorífica. Contiene una sustancia que parece goma, una resina roja, amarga y acre, una sustancia parecida al almidón, ácidos málicos y silícicos, cloruros de sodio y materias colorantes.

(11) *Chiquichique* (*Cassia indecora*, *leguminosas*).—Se usa el zumo y el cocimiento de las hojas y flores como febrífugo, en bebidas y lavativas. Contiene mucho mucílago y se recomienda especialmente para el tratamiento de las fiebres biliosas.

(12) *Coco* (*Cocus nucifera*).—La cubierta fibrosa de la nuez contiene tanino y gran cantidad de aceite. El perispermo de la fruta contiene albumina, un aceite fijo, goma, azúcar no cristilizable, sustancia colorante, fibrina, caseina y agua. El agua de coco se usa como diurético, especialmente adicionada de ginebra, contiene azúcar, albumina y agua. Del fruto verde se prepara un jarabe de gusto agradable y que recomiendan como pectoral. (Véase la fórmula.)

(13) *Conopia* (*Rencalmia, sylvestris*).—El pericarpio del fruto da una tinta morada. Se prepara un aceite usado como resolutive y calmante.

(14) *Cruceta real*.—Arbol mediano que crece con abundancia en todo el oriente de la república, donde goza de mucha fama como amargo estomático y febrífugo. El Dr. E. Fernández lo ha usado en Caracas para el tratamiento de las fiebres intermitentes inveteradas, con buenos resultados.

(15) *Congrina*.—Esta sustancia tiene propiedades antireumáticas de gran valor, machacada y puesta en maceración con alcohol, obra eficazmente en los dolores musculares.

(16) *Dividive* (*Cesalpineia coriara*, *Cesalpinaceas*).—Los frutos contienen de un 30 á 40 por ciento de tanino. El polvo y el cocimiento se usan con ventaja en las gangrenas, en las cardialgias y dispepsias, y tiene las demás aplicaciones de los tánicos.

(17) *Durazno*.—El cocimiento de las hojas de esta planta se usa en las afecciones herpéticas y en el exema.

(18) *Eneldo* (*Foeniculum vulgare*, *Anethum fœniculum*).—En los cólicos ventosos ejerce notable acción la infusión de esta planta, especialmente en los niños de pecho, asociado al bicarbonato de soda ó la magnesia.

(19) *Espadilla* (*Crotalaria stipularia*, *leguminosas*).—Yerba de más de media vara de altura, habita sobre las colinas secas, da flores amarillas, sus frutos son legumbres de algo más de media pulgada de largo, oblongadas, sin divisiones y con varias semillas de forma semilunar, prendidas á la sutura superior de la legumbre. Se usa como antiflogística y sudorífica, el zumo de las hojas, en el tratamiento de las fiebres inflamatorias y en el de las insolaciones.

(20) *Esponjilla* (*Luffa purgans*, *cucurbitaceas*).—Planta rastrera y abejucada, habita lugares cálidos y húmedos. El tegido reticular exterior puesto en infusión con agua caliente, hasta que tome un gusto amargo, es purgante enérgico. Se usa como antireumático, como contraveneno general y en el tratamiento del tétano.

(21) *Escorzonera* (*Craniotaria annua*).—Planta con flores muy bellas que exhalan un olor almizclado bastante fuerte y fastidioso. La raíz perpendicular y gruesa está cubierta de una corteza negruzca que se rompe con facilidad, dejando al descubierto una película amarilla que es la parte más exterior de la corteza, la cual es blanca y blanda y de una á dos líneas de espesor; la parte carnosa de la raíz también es blanca y de un sabor acuoso y dulce. Se usa el zumo, el cocimiento y un jarabe, recomendándola como laxante, emenagoga y antisifilítica.

(22) *Fregosa* (*Capraria biflora*, *escrofularinas*).—Se usan las hojas en infusión y cocimiento como sudorífico y el zumo como antidisentérico, sobre todo en enemas. Posee un principio estimulante, análogo por sus efectos á la terna. Tomada en grandes cantidades produce embriaguez, debilidad general, somnolencia, debilidad de la memoria y hasta vértigos.

(23) *Guácimo* (*Guazama ulmifolia*, *bitueriáceas*).—Su corteza, muy cargada de mucílago, se usa como emoliente y emenagogo, preparada por simple maceración en agua.

(24) *Guatamare Cereipo* (*Microspermo frutecens*, *papilionaceas*).—Sus frutos son aromáticos y agradables; se usan en tintura y en aceite como anti-espasmódicos y anti-reumáticos.

(25) *Guaritoto* (*Yatopha urens* y *Vitifolia*).—Se usa para la urticación y sus raíces son un poderoso hemostático.

(26) *Gengibre* (*Zingiber officinale*, *zingiberaceas*).—La raíz de esta planta nudosa, tuberosa, de un color amarillo y de un sabor picante, se usa en infusión como carminativo y estimulante de los órganos digestivos.

(27) *Guaco* (*Planta del genero Mikanica*).—Se emplean tres especies de guaco, el morado (*M. radicans*), el blanco (*M. scandens*), el verde (*M. Gonoclada*), de las cuales la más estimada es la primera, en la cual predomina un principio amargo; en la segunda, uno aromático, y en la tercera, uno astringente. Se usan las hojas y los tallos en zumo, cocimiento, tintura, extracto, etc. Es un agente poderoso preconizado como preservativo y curativo de las mordeduras de culebra, y el tónico de preferencia en los estados supuratorios.

(28) *Llantén* (*Plantago major*, *plantagineas*).—Se emplea el cocimiento ó el zumo de las hojas como detergente y astringente en las úlceras, flujos sanguíneos serosos y purulentos.

(29) *Merey* (*Anacardium occidentale*, *anacardicas*).—Planta muy cultivada en América y en las Indias Orientales. Se emplea el fruto y el pedúnculo piriforme, rico en un jugo muy astringente. Del fruto se extrae por expresion un aceite esencial contenido en su mesocarpo, y el cual está dotado de propiedades causticas que utilizó, siempre, el Dr. D. Beauperthin, notable médico del oriente de la república dedicado al estudio de nuestras plantas, y que escribió una excelente monografía sobre la lepra; la principal aplicación que él hacía de este cáustico era para destruir los tubérculos de los leprosos. Dicho aceite es líquido, trasparente, algo viscoso, insoluble en la agua, muy soluble en el alcohol sea frío, sea hirviendo, en el éter, aceites fijos, y grasas. El amoniaco y el agua de sosá ó potasa cáustica lo disuelven con facilidad, y tratado por un ácido mineral se obtiene una sustancia sólida, algo soluble en el agua y ácida probablemente el ácido anacárdico. A la parte cáustica del aceite le ha dado Hoedler el nombre de cardol. Se usa como cáustico y vesicante y reemplazaría con ventajas á las cantáridas. Creemos que esta sustancia merece que se estudie con detención.

(30) *Mango* (*Mangifera indica*).—Tanto el fruto como las demás partes del árbol contienen cierta cantidad de tanino, un líquido resinoso, sin color, y con olor análogo á la trementina, el cual sale por las cortaduras hechas en la corteza del árbol ó en los frutos verdes; su sabor es quemante; se espesa expuesto al aire; pero no se solidifica. De la corteza usada como febrífuga, asegura el Dr. Dumontel de San Tomás, haber extraído una sustancia á la cual le dió el nombre de

*mangotina*, y la cree superior á la quinina en el tratamiento de las fiebres intermitentes. Con el fruto se prepara un jarabe pectoral, y con las semillas otro muy encomiado para el tratamiento de las diareas crónicas.

(31) *Orégano* (*Lippia micromera*).—Esta planta aromática, anti-espasmódica, es áltamente estomacal, y se usa con ventajas en la disuria espasmódica.

(32) *Pasote* (*Chenopodium ambrosioides*, *salsolaceas*).—Domina en esta planta un principio aromático, nauseabundo y muy picante. Se emplea el zumo ó la infusión de las hojas contra las indigestiones, y se prepara un aceite anti-helmíntico. En cataplasmas como resolutivo.

(33) *Piñón* (*Jatropha curcas*, *euforbiaceas*).—La almendra de esta planta encierra un aceite acre de acción vomipurgante enérgica.

(34) *Raíz de mato* (*Aristolochia barbata*, *aristolochias*).—Se usa con gran ventaja en todas las hemorragias, principalmente en las que se producen en las fiebres infectivas, como la remitente hemorrágica, amarilla, disentérica, gangrenosa y fiebre hematúrica. Tiene propiedades estimulantes y astringentes y un principio aromático. Es superior á la trementina y á otros astringentes, según el Dr. J. M. de los Rios. De esta planta solo se usa la raiz, bajo la forma de infusión, tintura y extracto.

(35) *Rosa de montaña* (*Brownea*, *leguminosas*).—La madera del tronco y las hojas contienen un principio astringente que la hacen utilizable en polvo y en cocimiento como astringente y hemostático.

(36) *Sauco* (*Sambucus virginiana*).—Las flores de esta planta usadas en infusión son sudoríficas, los tallos y las hojas tienen propiedades vomipurgantes, y entra en la poción conocida con el nombre de antidisentérica, cuya benéfica acción diariamente explotamos y que ha sido vendida por tanto tiempo como remedio secreto con el nombre de “Específico del Dr. Laloubie.”

(37) *Totumo* (*Crescentia cryete*, *crescentiaceas*).—Se utiliza el fruto para la preparación de un jarabe muy recomendado en la tisis, abcesos hepáticos, y contusiones internas.

(38) *Torco*.—El polvo de esta planta se usa en la gastralgia y en todas las formas de dolores espasmódicos también se aplica en la diarrea atónica.

(39) *Tamarindo* (*Tamarindus indica*, *leguminosas*).—La pulpa del fruto del tamarindo se usa como laxante y atemperante. Es de un color rojo oscuro, de un gusto ácido azucarado; entra en la composición de la conserva de Vargas, preparación del célebre médico venezolano de este nombre, y que se aplica con excelente resultado para el tratamiento de las afecciones hepáticas.

(40) *Túatúa* (*Yatropa gossipifolia*, *euforbiaceas*).—Se usa con frecuencia la infusión de esta planta como laxante, y según la energía con que se quiera obrar se aumenta la dosis.

(41) *Verdolaguilla*.—Esta planta crece en los tejados, tiene un principio amargo pronunciado, y es muy usada como diaforética y febrífuga en las formas maláricas no muy intensas.

(42) *Yerba mora* (*Solanum nodiflorum*, *solariaceas*).—Esta planta tiene propiedades narcóticas, y se usa en cataplasmas con sustancias grasosas, en todos los casos en que es necesario atenuar el dolor con aplicaciones locales, dando muy buenos resultados en el tratamiento del herpes, zona, erisipelas, etc.

(43) *Yagrun* (*Ceropia peltata*, *artocarpeas*).—Se usan las hojas, yemas y parte leñosa del tronco del yagrumo morado, recomendándolo como sucedaneo de la digital. Esta planta ha sido estudiada especialmente por el eminente Dr. G. Michelena, el cual refiere haberla usado siempre con muy buen resultado para disminuir el número de los latidos cardiacos. En el asma lo usaba mucho el Dr. Antonio Rodríguez, catedrático de terapéutica y materia médica, y el Dr. Rísquez lo usa como antiasmático, cuando hay intolerancia por el yoduro de potasio. La planta es muy mucilagínosa, y no se ha podido encontrar en ella ningun alcaloide.

(44) *Yuca* (*Manihot utilisima*, *euforbiaceas*).—La raíz de esta planta contiene una gran cantidad de fécula, y un principio venenoso (ácido cianhídrico) que se separa por el lavado, el fuego y la fermentación. De ella se extrae el almidón, que reemplaza en Venezuela el almidón de trigo; y con sus rasuras se prepara el pan llamado cazabe, empleado para cataplasmas.

## PREPARACIONES MÁS USADAS.

Los jarabes de las sustancias antes mencionadas se preparan con 400 gramos de la sustancia madre, 4,600 de agua y 11,500 de azúcar; se pone todo al fuego y se reduce á la mitad. El jarabe de coco se prepara en el fruto mismo, agregándole 500 gramos de leche de vaca y 240 gramos de azúcar; se tapa bien y se hierve en baño maría por media hora. El jarabe de tortumo se prepara introduciendo en el centro del fruto, previamente dividido á través de una abertura practicada en la corteza, dos ó tres cucharadas de vinagre y otras tantas de miel de abejas. Se pone á la parilla ú horno, y cuando se ha reblandecido el fruto, se separa y esprime filtrando.

| Muriato de cocaína ..... | .10 |                                       |    |

M. Agítese antes de usarse. Una cucharadita por dosis. Dr. Rísquez.

*Poción febrífuga.*

|                                  |     |                          |   |
|----------------------------------|-----|--------------------------|---|
| Muriato de quinina soluble ..... | 3   | Tintura de acónito ..... | 3 |
| Agua destilada .....             | 180 |                          |   |

M. Una cucharada cada 3 horas en la fiebre remitente con energía del corazón : la misma fórmula con tintura de digital, en vez de la de acónito, si hay atonía de dicho órgano. Dr. J. M. de los Ríos.

## INDIGENOUS DRUGS OF CENTRAL AND SOUTH AMERICA.

By ADOLPH W. MILLER, M. D., PH. D.

By far the most important and valuable contribution made for centuries to the storehouse of materia medica has been furnished by the primeval forests of South America. The tree named after the pious and charitable Countess of Chinchon has proved itself to be a veritable blessing to suffering mankind. It has made human existence possible in the jungles of India, in the fever-stricken Campagna of Italy, in the lowlands and marshes of Holland, in the territory of the bayous of our sunny South. Without it, many of the present homes of modern culture and civilization would inevitably sink back into barbarism. It is recognized as an indispensable necessity for the explorer of the interminable forests covering the interior of Africa. Not even the fertile brain of a Rider Haggard dared to send his hero into "*Africa horrida sylvarum*" without an abundant supply of quinine. Truly it fully merits the title that has been aptly bestowed upon it—"the tree that is for the healing of the nations." Ipecac root and jaborandi leaves from the dense forests of Brazil; balsam of Peru from the *Costa del Balsamo*; jalap root, the *ruybarbo de las Indias*, from the Mexican Andes; sarsaparilla root from Central America; and coca leaves from Peru and Bolivia have been accepted into the official pharmacopœias of most of the civilized nations. Their therapeutical virtues are thoroughly recognized and their consumption is enormous. The collection and preparation of these important drugs naturally adds materially to the wealth of the countries producing them. The prodigious richness of the Central and South American flora, which has furnished us so many highly valuable therapeutic agents, unquestionably conceals many further treasures from the discovery of which the medicine of the future will profit to the glory of science and the welfare of humanity. When the enormous extent and great fertility of the vast countries south of the United States are considered, it is somewhat surprising that the medical resources indigenous to them have of late years received comparatively little attention. It is well known that almost innumerable varieties of medicinal plants exist there in great profusion, and that the aborigines have from time immemorial made use of them. At rare intervals the attention of the profession has been directed to a few of these drugs, but the difficulties of obtaining regular supplies in sufficient quantities have so far proved an almost insurmountable barrier to their general introduction. It is also quite possible that the spirit of commercial enterprise which characterized the introduction of some of these new medicinal agents may have prejudiced many minds against them. Without a doubt many of these drugs were extolled far beyond their intrinsic merits, and frequent disappointment was then a natural sequence. It would therefore seem to be an eminently proper task for the Pan-American Medical Congress to consider the desirability of the diffusion of more accurate and definite knowledge of those medical productions of Central and South America that have not so far received the full measure of attention that they would seem to deserve. The noble and ideal aim of the American Republics should tend toward the establishment of such reciprocal relations that the chemical and pharmaceutical productions of our splendidly equipped Northern laboratories could be exchanged for equal values of rude drugs furnished by the virgin soil of Mexico, Honduras, Guatemala, and all of South America. The sufferers and the afflicted of all nations and climes, the great army of the lame, the halt, and the fever stricken, would be the true gainers of such fraternal and equitable traffic. The careful preparation, promulgation, and general recognition of a Pan-American pharmacopœia would be a very important step in this direction. Its acceptance by the members of the medical and pharmaceutical profession in the sister Republics would be of very great value in fostering feel-

ings of mutual esteem and friendship. Even if such an official publication would confine itself to the more active and energetic preparations, where uniformity of strength and dose is highly important, it would still be of immense and constantly increasing value in view of the rapid advances in our modes of travel and communication.

The following memoranda on a few of the lesser-known drugs of Mexico and Central and South America have been collected chiefly for the purpose of presenting in a classified form a synopsis of the recent literature of this branch of the study of materia medica. The number and extent of these notes, which have been condensed as much as possible, may serve as an index of the importance of this subject. The constant aim in their preparation was to extract only points of interest to the general practitioner, and to omit details of chemical, microscopical, pharmaceutical, and botanical investigations. The plants are presented in the order of their botanical relationship according to the arrangement of Prof. Asa Gray.

#### MAGNOLIACEÆ.

*Coto bark*.—Ever since the introduction of coto bark into Europe, in 1873, the true botanical origin of this valuable drug has been a matter of diligent inquiry. Dr. Theodor Schuchardt at last succeeded in obtaining the botanical material; flowers, fruit, leaves, and branches, necessary for the determination of the source of the true coto bark. Dr. Karl Schumann announces this to be *Drimys Winteri*, Forst., var. *granatensis*, Eichl. This tree is a native of the Province de los Andes of Venezuela, growing at altitudes of 2,500 to 3,000 meters, near to the borders of the United States of Colombia. (Amer. Drugg., Feb. 1, 1891, p. 37.) The tree is therefore botanically very closely related to the *Drimys Winteri* which furnishes Winter's bark. This drug was first brought to England toward the end of the sixteenth century by Capt. Winter, who accompanied Drake on his voyage around the world. At that time it was obtained from the Straits of Magellan, but it was also met with as far north as Chile. True coto bark appears to be an aromatic drug of great promise in the treatment of diarrhœa and colic. It has been subjected to very careful chemical examinations by Wittstein, Jobst, and Hesse, who have succeeded in isolating a number of active principles from it. The most important of these is cotoin, which has been given in doses of three-fourths grain by Dr. Burkart. Its value in the treatment of diarrhœa has been confirmed by various clinicians. Paracotoin, an analogous active principle extracted from so-called paracoto bark, is claimed to have been successfully used by Prof. Balz, of Tokio, Japan, in the treatment of Asiatic cholera, for which purpose 3 grains were injected hypodermically. The crude powdered bark and an alcoholic tincture prepared from it proved to be specifics for diarrhœa in the hands of Dr. von Gritte. Based on their physiological experiments, Dr. von Gritte and Dr. Burkart, however, claim that both the true coto and the paracoto barks are objectionable in their crude form on account of their secondary action on the stomach, but they confirm the specific virtues of cotoin and paracotoin as remedies for diarrhœa. (Liebig's Annalen, p. 199.) Most of the commercial supplies of coto bark are furnished by Bolivia.

#### MONIMIACEÆ.

*Boldo*: *Peumus boldus*, Molina, 1782; *Rinzia fragrans*, Pav.; *Peumus fragrans*, Pers.; *Boldoa fragrans*, Gay; *Boldoa fragrans*, Sul. An evergreen shrub found in the mountain meadows of the Chilean Andes. Its yellowish-green fruit is edible, its bark is used in tanning, and its wood in the making of charcoal. The leaves contain a large amount of volatile oil in special cells, and they are the part used in medicine. MM. Bourgoïn and Verne separated a peculiar alkaloid from them, which they named boldine. P. Chapoteaut has also obtained a glucoside

from them, on which he bestowed the title boldoglucin. This is said to act as a narcotic on the lower animals. It was administered with apparent success by Dr. René Juraviller as a calmative and hypnotic remedy in a case of insanity. An essential oil has also been obtained from boldo by distillation, which produced warmth in the epigastrium in doses of 15 minims; half a dram of it gave rise to considerable gastric irritation, with pain and vomiting. A strong smell of the oil was then imparted to the urine. Dujardin-Beaumetz has employed 5-drop doses of it advantageously in genito-urinary inflammation. The leaves have also been used in France as a tonic in chronic hepatic torpor and in hepatitis. For this purpose 8 minims of a 20 per cent alcoholic tincture have been given at a dose, which was gradually increased. Large doses are apt to induce emesis and purgation. In South America the drug is used in gonorrhœa and in chronic catarrh of the bladder. The commercial supplies of boldo leaves are now mostly obtained from the cultivated districts. The shrub is never found in forests, nor outside of Chile. It attains a height of 5 or 6 meters, and it has cylindrical, opposite branchlets. The leaves are reddish brown in color, entire, oval, opposite, coriaceous, with prominent midrib. They have a fresh aromatic taste and odor, recalling that of the *Lauraceæ* and *Labiataæ*. The Chileans make necklaces and rosaries of the very hard kernels of the fruit. M. Claude Verne has published formulas for an extract, sirup, tincture, wine, and elixir of boldo, all of which have been employed in the Hôtel-Dieu and Hôtel Beaujon in cases of atony of various organs, when the patients have been unable to tolerate quinine. Large doses were, however, followed by vomiting. (Ph. Journ. Transc., Nov. 21, 1874, p. 405; Am. Journ. Pharm., Nov., 1884, p. 580.) Dr. Charles W. Zaremba states that at a conference of the Sociedad Medica of Santiago de Chile the following summary of the therapeutics of boldo was accepted: Boldo is a most useful and profitable remedy in blenorrhagia. It gives good results in dyspeptic affections, when these are due to atony or debility of the digestive organs, or when they are complicated by bilious disorders. The administration of boldo is often advantageous in catarrh of the bladder. Boldo is an important auxiliary in the treatment of hepatic abscesses, when the febrile symptoms have been overcome. Powerful anthelmintic virtues are also claimed for boldo. (Parke, Davis & Co.'s Brochure No. 8.)

## ANONACEÆ.

Fruto de Burro: *Xylopia longifolia*, D. C. The long-leaved bitter tree flourishes throughout the valley of the Orinoco. Its fruits enjoy quite a reputation there as a febrifuge. They possess a distinct peppery taste and odor, faintly recalling that of allspice. A chemical and microscopical examination of the fruits exhibited in Vienna that had been obtained from Guiana by way of Venezuela was made by T. F. Hanausek, and it established the presence of a volatile oil, a soft resin, tannin, and indifferent bodies. It would seem to be valuable as an aromatic tonic, or a culinary spice. (Zeltschr. d. Oestr., Apoth. Ver., Dec. 10, 1877, p. 571.)

## VIOLACEÆ.

Cipo-zumo: *Anchietea salutaris*. Dr. Theodor Peckolt describes this as a useful medical plant frequently met with in Brazil. He claims various purgative and antisiphilitic virtues for it.

## FRANKENIACEÆ.

Yerba reuma: *Frankenia grandifolia*, Cham. and Schlecht. The Spanish name, meaning flux herb, implies that this plant is chiefly used in catarrhal affections. Yerba reuma is an erect or prostrate leafy undershrub, 6 to 12 inches high, found on the seashore from San Francisco to San Diego and southward, also eastward in

the desert to Arizona and southern Nevada. It has been subjected to chemical and microscopical examination by Carl Jungh, Ph. D., of Detroit, Mich. (New Preparat., March, 1879, p. 55.) It was found to contain a peculiar astringent principle, and a remarkably large percentage of sodium chloride. Its value as a topical application is largely attributable to this combination. Dr. F. C. Herr gives the results of the use of this drug in a number of cases. (Therap. Gaz., 1883, p. 315.) He employed a fluid extract and a tincture of yerba reuma with marked success in the local treatment of nasal catarrh, gonorrhœa, leucorrhœa, coryza, ozœna, gleet, and chronic inflammations of the mucous membranes in general. He also found the fluid extract of yerba reuma to act admirably as a local application in herpes zoster. (Parke, Davis & Co., Brochure No. 59.)

## TAMARISCINEÆ.

Ocotilla: *Fougnieria splendens*. This fan-shaped tall shrub abounds on the table lands of the Mexican boundary line, where it is known by the Mexican name of ocotilla. The bark has been chemically examined by Dr. Helen C. De S. Abbott. A peculiar new wax was obtained, differing in its properties from other known vegetable waxes. The name of ocotilla wax was proposed for this product. A white crystalline substance, a gum resin, and possibly glucosides, were also indicated. (Am. Journ. Pharm., Feb., 1885, 81-85.)

## MELIACEÆ.

Cocillaña: *Guarea Rusbyi* (Britton). Out of several hundred native remedies examined by Dr. H. H. Rusby during his explorations in South America, this is the second one that he has so far proposed as meriting the careful attention of the medical profession. The physiological and clinical investigations made with the drug indicate a high remedial value for it. Dr. Rusby discovered cocillaña in 1886 in Bolivia, the drug being the bark of an undetermined species of *Guarea*. Dr. Nathan L. Britton at first erroneously assigned it to the natural order of the *Anacardiaceæ*, and he described it under the name of *Sycocarpus Rusbyi*. Subsequently it was referred with some doubt to *Guarea trichlinoides*, Linn. The tree reaches a height of 30 to 40 feet, with a trunk diameter of nearly 3 feet. It is low and spreading in its habit, somewhat resembling an apple tree in its general looks. The therapeutic properties of cocillaña appear to be those of an expectorant, tonic, and laxative. Its sphere of action and influence is somewhat similar to that of ipecac, but it seems to be superior to the latter in certain diseases of the air passages. Clinical experience has also established the fact that it exerts a tonic influence on the appetite, and that it reduces the night sweats of chronic bronchitis and phthisis. The fluid extract is an eligible preparation administered in doses of 10 to 30 minims. Cocillaña has been the subject of very careful botanical study by Dr. Nathan L. Britton, of Columbia College. (Bulletin of the Torrey Botanical Club, July, 1887.) Joseph Schrenk has published pharmacognostical and microscopical notes on its structure and appearance. (Drug. Bullet., Aug., 1888, p. 222.) Dr. H. H. Rusby has prepared an elaborate account of its physiological action and therapeutic history. (Therap. Gazette, Aug., 1888, p. 518.) Numerous clinical studies of cocillaña have been recorded by Dr. Reynold W. Wilcox and other practitioners. The results of these investigations would seem to warrant the claim that while the action of this drug is in some respects similar to that of ipecac, it is still sufficiently distinct from that, and from all others, to constitute a drug of an entirely new action, one which will not fall into line with any other. (Parke, Davis & Co.'s Brochure No. 17.)

## LINEÆ.

*Erythroxylon pulchrum*, St. Hil. This near relative of the well-known Erythroxylon Coca seems to have received but little attention so far. It is met with abundantly in the mountainous region about Rio de Janeiro. Mr. Theodor Pecolt has experimented with this Brazilian species of Erythroxylon, and has obtained from the fresh leaves a very small percentage of cocaine, a strongly bitter extractive principle, and a crystallizable acid. These leaves would seem to deserve a careful therapeutic study.

## SIMARUBEÆ.

Cedron seed: *Simaruba cedron*, Planchon. The cedron tree appears to be confined to the United States of Colombia, ranging from the fifth to the tenth degree of north latitude, and from 75° to 80° of west longitude, but is always rather rare. The drupaceous fruit is about the size of a swan's egg, and has the appearance of an unripe peach. Each drupe contains one seed, the cedron of commerce, which is easily separated into two large cotyledons, resembling blanched almonds, but larger in size, and plano-convex in contour. Leroy, in 1851, discovered a bitter principle in the seeds which he named "cedrine." More recently Tanret has isolated from them an alkaloid of very great activity, cedronine, the dose of which is a milligram. Cedrine was also found to be poisonous in large doses. Cedron seeds have been used extensively by the natives and the physicians of Mexico and Central America. They are so intensely bitter that a fluid or solid extract is generally preferred to the crude drug. The dose of the fluid extract is stated at 1 to 8 minims. The drug is used as a remedy for the bites of insects and serpents; for hydrophobia; it is of service in intermittent fever, dyspeptic affections, cholera morbus, colic, facial neuralgia, and gout. Almost incredible reports have been published of its marvelous effects in the treatment of hydrophobia and the bites of venomous reptiles, such as rattlesnakes, moccasins, copperheads, and tarantulas. It is claimed for cedron that it possesses tonic, antiperiodic, and antispasmodic virtues of so decided and pronounced a character that the drug is fully entitled to a prominent place in the classification of the materia medica of the future. (Parke, Davis & Co.'s Brochure No. 25.)

*Cascara amara Picramnia*, spec. indet.; also known as Honduras bark. The plant furnishing this bark is indigenous to Mexico, Honduras, etc. It has been chemically examined by F. A. Thompson, who procured an alkaloid from it, for which he suggested the name of picramnine. (Am. Journ. Pharm., 1884, p. 390.) This active principle has the peculiar taste of the bark, and is believed to represent its virtues. Numerous clinical reports on cascara amara tend to confirm its value as an alterative. It is credited with achieving cures of chronic cases of syphilitic eruptions, syphilitic tubercles, chronic eczema, and gummy tumors. Although slow in its action, it is regarded almost as a specific in syphilis. The assertion is made for it that it eliminates the specific poison from the system. The fluid extract is given in doses of one-half to 1 dram, and the powdered extract in doses of 5 to 10 grams. An illustration of Honduras bark and a number of clinical reports on it are given in Parke, Davis & Co.'s Brochure No. 12.

## ZYGOPHYLLACEÆ.

Creosote wood: Tah-sun-up of the Pah-Ute Indians. *Larrea Mexicana*. It is quite common in southern California, Lower California, Arizona, and southern Utah. An infusion of the plant is used with benefit for open sores on men and animals. The powdered leaves are said to be valuable as an application to chronic sores. A peculiar gummy substance exudes from the old wood in abundance, and is used by the Apaches as a styptic. The peculiar odor of the fresh plant has earned for it the name of creosote wood. (Dr. E. Palmer in Am. Journ. Pharm., Dec., 1878.)

## RUTACEÆ.

*Xanthoxylum Naranjillo*, De Cand., is used in the Argentine Republic as a sudorific and diuretic. Parodi has found a volatile oil and an alkaloid in it. (Am. Journ. Pharm., 1890, p. 177.)

*Jaborandi*.—Two varieties of this valuable drug have received the official recognition of the seventh decennial revision of the United States Pharmacopœia, namely, the leaflets of the *Pilocarpus Selloanus*, Engler (Rio Janeiro jaborandi), and those of *Pilocarpus Jaborandi*, Holmes (Pernambuco Jaborandi). In addition to the drug in its crude form, the new pharmacopœia also recognizes the fluid extract, and the hydrochlorate of the active alkaloid, pilocarpine. Jaborandi is so powerful and so certain in its diaphoretic action that it now ranks as the most reliable and influential remedy of its class. In fact, so great is its power that it has very considerably extended the use of diaphoretics. It has rarely occurred that a new remedy has been so very generally accepted, and so universally introduced in so short a space of time as jaborandi, which was first brought to the notice of the profession in 1874 by Dr. Coutinho, of Pernambuco.

*Brazilian Angustura bark*—*Esenbeckia febrifuga*, Mart. The bark of a plant found on the coast range of Brazil. It has been chemically examined by Buchner and by von Karl am Emde. A nitrogenous base, named Esenbeckina, was obtained from it in a crystallized form. The pure alkaloid, as well as its hydrochlorate, were found to be highly deliquescent when exposed to the air. (Arch. Pharm., 193 B., 2 Hft.)

## OLACINEÆ.

Muirapuama. *Liriosma ovata*, Miers. Brazilian correspondents of Messrs. Parke, Davis & Co. assure them that this root is more highly esteemed as an aphrodisiac and nerve stimulant in Brazil than damiana is with us. A fluid extract is recommended, in doses of  $\frac{1}{4}$  to 1 dram. (Parke, Davis & Co.'s Brochure No. 47).

## ILICINEÆ.

Yerba maté; Cha-maté; Paraguay Tea: *Ilex paraguayensis*, St. Hil. The prepared leaves of this, and most probably also of several other allied species of *ilex*, form an important article of the daily food of a vast number of the inhabitants of South America. Their therapeutic effect is due chiefly to the caffeine which they contain in relatively large proportion. The infusion of the leaves, used as a beverage in place of tea or coffee, is regarded as an exhilarant, acting as a cerebral stimulant, but inducing indolence and drowsiness subsequently. The usual mode of its preparation consists in pouring boiling water upon the prepared dried leaves. The infusion while still hot is sucked up, frequently from a common bowl, through a silver tube known as a "bombilla." This instrument is furnished at the lower end with a perforated bulb, which prevents the ingress of the coarsely crushed leaves by straining them out.

## RHAMNACEÆ.

*Zizyphus mistol*, Griseb. Indigenous in the Argentine Republic. The fruit is claimed to have diuretic properties.

Piquillin: *Condalia lineata*, Griseb. Also met with in the Argentine Republic. The inspissated juice has been used as a laxative for children.

Quina del Campo: *Discaria longispina*, Miers. A rare Brazilian bush, covered with spines, the roots of which have antifebrile properties.

## SAPINDACEÆ.

Timbo: *Paullinia pinnata*, Linn. A Brazilian plant closely related to the well-known tree which furnishes guarana. The bark is the only part of the timbo root used in Brazil. It has an aromatic, agreeable odor, which slightly resembles that of musk. Poultices made from it with boiling water are applied externally for affections of the liver. They often produce so intense an eruption that it becomes necessary to discontinue their use. Mr. Martin has isolated an alkaloid from timbo bark which he has named timbonin. He has also succeeded in crystallizing the sulphate of timbonin in white needles. (Bull. Gén. de Thérap.) Other plants are also known as timbo.

## POLYGALACEÆ.

Yallhoy: *Monnina polystachya*. A pretty plant, extensively distributed, growing near the summits of steep mountains in South America, as well as on the wooded plains and marshy districts of the same region. Therapeutic virtues have been attributed to two parts of the plant, the bark of the root and the recent leaves. The latter are regarded as an expectorant, whilst the former is considered to be an astringent. The root is of large size, 16 to 18 inches in length and of yellowish color. Its taste is at first sweetish, but afterwards it becomes acrid, bitter, and exciting the flow of saliva. The infusion is turbid, like soapy water. The drug can be given in the form of powder or infusion in doses of 10 to 12 grams per day. A 25 per cent tincture made with alcohol and ether has also been recommended, as well as an ointment made from the extract of monninia. (Etudos Medicos, No. 4, Practitioner.)

## LEGUMINOSÆ.

Resina d'angelim pedra is used in Brazil as a febrifuge. It is believed to be obtained from *Ferreira spectabilis*, and seems to be identical with the so-called rhatanin found by Dr. Emil Ruge in the South American rhatany extract. (Zeitschr. d. oestr. Apoth.-Ver., 1869, 32.)

Araroba (*Goa powder*).—The tree from which this powder is obtained is known as the *Angelim amargoso*. It is the *Andira araroba* of Aguiar. The powder furnishes a neutral principle, the chrysarobinum, which is officinal in the United States Pharmacopœia. It is extensively employed in the treatment of cutaneous affections, for which purpose the *Unguentum chrysarobini* has also been adopted in the United States Pharmacopœia.

Chanar: *Gourliea decorticans*, Gill. A drug from the Argentine Republic, where the inspissated juice of the fruit is used in pectoral affections.

*Prosopis tintitaco*.—Also from the Argentine Republic. The fruit is reputed to have diuretic properties.

*Resina de Angico*.—A product of the district of Maranhão; is misnamed a resin, as it is in reality a gum of deep brownish-red color, translucent, and breaking with a shining fracture. Chirnoviz assigns it to the *Acacia angico*, and claims it to be of value in pectoral complaints. The same tree yields an astringent bark. With twice its weight of water, the gum forms a thick magma. It dissolves in proof spirit almost as well as in water. The aqueous solution is rendered turbid by ammonium oxalate, but it is not affected by ferric chloride, borax, or plumbic acetate. (Yearbook of Pharmacy, 1882.)

Cumanda viray: *Calopogonium cœruleum*, Benth. An herb met with abundantly in the Argentine Republic and other parts of South America, where it is employed as an aperient febrifuge.

Urizuhei: *Rhynchosia diversifolia*, Mich. Used in the Argentine Republic as an expectorant, and as a remedy for spasmodic coughs.

Yerba del toro: *Crotalaria incana*. A common herb of the Argentine Republic, where it is used for making an aromatic tonic tea, which is popularly used for stomach-ache, and also as a perfume.

Mezquite: *Algarobia glandulosa*. The tree yields a gum, which has frequently been used as a substitute for gum arabic. Mezquite leaves have been employed with great success in the treatment of inflamed eyes. They are also of value as a cataplasm for inflamed surfaces. In the form of hot infusion they are given as a febrifuge in mild fevers. The legumes act as simple laxatives; they are also of great value as a food for cattle. The Mexicans prepare a pleasant beverage from them, called "atole." This is simply an infusion made by throwing the crushed ripe berries into boiling water, or by boiling them together, and subsequently straining. A fermented liquor is also made in Mexico from the fruit, which readily undergoes alcoholic fermentation. The decoction of the heartwood of the tree is used in diarrhœa, being a valuable remedy in this and similar complaints. (Am. Journ. Pharm., Feb., 1890, p. 65.)

*Panbotano bark*.—Prof. Dujardin-Beaumetz calls attention to the panbotano tree of Mexico as a new specific for the fever and other symptoms of paludism. No alkaloid or glucoside has so far been found in the bark. Valude administered an alcoholic tincture and a concentrated decoction, preferring the latter. Seventy grains of the bruised bark were administered in twenty-four hours. In the 8 paludic cases described by Valude a single dose, or at most two doses, was sufficient to cause the disappearance of well-defined tertian fevers. (Nouveaux Rem., Mar. 8, 1890.)

Jamaica dogwood: *Piscidia erythrina*, Linn. The bark of the root is the part employed in medicine. The tree is met with in the West India Islands and on the adjacent mainland. Attention was first called to the drug in 1844 by Dr. William Hamilton, who recommended it as a powerful narcotic, capable of producing sleep and relieving pain to an extraordinary degree. About 1878 it was more carefully worked up as to its physiological action and therapeutic effects by numerous experimenters. It is without doubt a very active drug, but its exact practical value does not yet appear to have been definitely settled. Various practitioners have reported good results from its use as an anodyne in neuralgia, nervous insomnia, whooping cough, etc., but in the hands of others the remedy has failed to be of benefit. The fluid extract seems to be a valuable application for certain forms of toothache. A very elaborate and carefully prepared monograph on Jamaica dogwood has been published by Parke, Davis & Co. in their Brochure No. 25.

#### ROSACEÆ.

Quillaja: *Quillaja Saponaria*, Molina. Soap bark has found official recognition in the United States pharmacopœia, together with a tincture made from it. The tree is a native of Peru and Chile, where it is known as Quillay, a term derived from the Chilean word quillean, to wash. Saponin, quillaiac acid, and sapotoxin have been isolated from it. At a meeting of German naturalists in Strasburg soap bark was proposed by Dr. Kobert as a substitute for senega root in pulmonary affections. He claimed that quillaja bark does not irritate the gastro-intestinal tract, that it quiets cough, increases the discharge of sputa, and that it is for these reasons even preferable to senega, which statements received general approval. Mr. Dimitry Pachurokow has devoted special attention to the study of the most active constituent of the drug, namely, the sapotoxin. This is present in the bark in only a very minute proportion, but it is exceedingly powerful. It is very remarkable for its peculiar action on the red blood corpuscles, which it dissolves completely, even in a dilution of one part in 10,000. This occurs only when the sapotoxin is introduced directly into the circulation by hypodermic injection. When injected in concentrated solution into an involuntary muscle it diminishes

or even entirely destroys its vitality. In spite of this toxic action, Pachurokow also defends the use of soap bark in place of senega on the grounds that its active constituents are more constantly present, and in nearly five times greater quantity. (Amer. Drugg., Apr., 1888, 72.)

## MYRTACEÆ.

Chekan, Chegnen, or Cheken : *Myrtus Cheken*, Molina. The leaves of an evergreen shrub or tree varying from 5 to 25 feet in height, found abundantly in the vicinity of Valparaiso, and also extending into Bolivia. It was introduced from Chile as a remedy of some value in the treatment of chronic catarrhal inflammation of the respiratory mucous lining. Dr. Murrell, of London, specially recommends it for the annoying and intractable winter cough of elderly people. Dr. Dessauer, of the German Hospital of Valparaiso, has obtained valuable results from its use in the purulent form of bronchitis. Other practitioners extol it as a desirable addition to the list of remedies in chronic bronchitis. Dr. F. Weiss, of Leipzig, Germany, obtained 1 per cent of an aromatic volatile oil from the dry cheken leaves. This was the only one of numerous constituents isolated by him that possessed a medical interest. Cheken has long been known and used in Chile in cases requiring an aromatic astringent of considerable power. The fluid extract of the drug seems to be an eligible mode of exhibiting its therapeutic effects. It is given in doses of 1 to 3 fluid drams. (Pharm. Centralhalle, 1882, No. 29.)

*Jambul*.—The seeds of *Eugenia Jambolana*, Lam. (*Sizygium Jambolanum*, D. C.), a tree native to tropical America, the West Indies, and the East. The bark, leaves, and fruit are used medicinally in India. The dried and powdered kernels of the seeds have been highly recommended as a valuable remedy in diabetes. They contain traces of volatile oil, resin, gallic acid, etc. (Pharm. Journ. and Trans., 1888.)

## MELASTOMACEÆ

Sulamita Vitullus? *Melastoma Ackermanni*. A new antineuralgic drug from Colombia. It is said to grow abundantly on the eastern spurs of the Cordilleras. The dried flowers of the plant have been used medicinally. When they were subjected to distillation a heavy essential oil was obtained from them which bore a marked resemblance in its odor to that of methyl salicylate, the chief constituent of the oil of wintergreen. (New Rem., Aug., 1883, 241.)

## LYTHRACEÆ.

*Icica-peré*.—A species of *Cuphea*, common in the Argentine Republic, where it is used as a purgative, diuretic, and alterative.

## PAPAYACEÆ.

*Southern papaw*.—The *Carica Papaya* of tropical America is sometimes classified among the *Passifloraceæ*. It has long been known that the unripe peeled papaw fruit has the property of rapidly softening the toughest meat when boiled with it for a short time. In Quito the use of the papaw juice for making meat more tender is quite general. The juice of the unripe fruit is also reported to be a powerful vermifuge. An albuminous digestive principle has been obtained from the fruit and has been named papain. This is now an article of commerce, and bears a resemblance to pepsin. Papain is at present used quite extensively as an internal remedy in dyspepsia and gastric catarrh; also as a local application for the destruction of false membranes, warts, tubercles, walls of old sinuses, and even of epithelioma and tattoo marks. It is neither caustic nor astringent, but it destroys the part to which it is applied by virtue of its power of dissolving the muscular as well as the connective tissue. Jacobi asserts that diphtheritic membranes may be dissolved in a few hours by the hourly application of a mixture of one part papain with two parts each of water and glycerin.

## CUCURBITACEÆ.

*Tayuya* or *Tayuia*.—A new Brazilian drug, which has been introduced and employed in France. It is probably the root of the *Bryonia Tayuya*, or *Trianosperma Tayuya*. The root is recommended in the treatment of syphilis. In small doses it acts as an emetic, in larger quantities as a drastic. (L'Union Pharm., Oct., 1875.)

Chili Cojote of the Mexicans: *Cucurbita perennis*. These large and long roots, after being macerated in water, are used with good effects in Mexico as an application to hæmorrhoids. (Dr. E. Palmer, Am. Journ. Pharm., Dec., 1878.)

## CACTEÆ.

Night-blooming Cereus: *Cirio de flor grande*; *Cereus grandiflorus*, Haworth. Indigenous to the West India Islands. This has been characterized as being the loveliest of all the cactus family. When in full bloom it has been poetically styled the "Queen of the Night." The drug has been highly recommended as a sedative and diuretic, with special application in functional diseases of the heart, accompanied by irregularity of its action. Benefit has also been derived from its use in palpitation, rheumatism, valvular disease, and dropsy. The alcoholic tincture is most frequently employed. Notwithstanding the numerous clinical reports in which the virtues of night-blooming cereus are lauded, some careful investigators have been unable to observe any effects from it. (Parke, Davis & Co.'s Brochure No. 14.)

## TURNERACEÆ.

Damiana: *Turnera microphylla*, D. C.; *Turnera aphrodisiaca*, L. F. Ward. A small mint-like herb, bearing a yellowish-white fragrant flower, growing near the western coast of Mexico. This is claimed to be a powerful aphrodisic, useful in cases of sexual atony. The natives are said to have made use of it for a long time as a stimulant to the sexual apparatus. Cholagogue, cathartic, and emmenagogue properties are also attributed to it. The published reports on the drug vary greatly as to its merits, some experimenters having had great success with it, while others reject it as being utterly useless. Some of these failures may be attributable to the frequent substitution of the leaves of *Haplopappus discoideus*, D. C., and *Bigelovia veneta*, Gray, for the true damiana. As early as 1699 the Spanish missionary Juan Maria de Salvatierra relates in his chronicles that the native Mexicans were in the habit of using damiana for impotency. An elaborate résumé of the literature of damiana has been published by Parke, Davis & Co. in their Brochure No. 23.

## UMBELLIFERÆ.

*Osha* root.—This Mexican umbelliferous root of unknown origin has been chemically examined by Hermann Haupt, jr. He obtained from it a resin, a fixed and a volatile oil, and an aromatic acid, resembling angelic acid. As it presented points of distinction from the latter, the name of oshaic acid was proposed for it.

## RUBIACEÆ.

*Trompetilla*.—The stem and branches of the *Rouvardia triphylla*, indigenous to Mexico, where it enjoys a reputation for the prevention and treatment of hydrophobia. A description of the drug has been published by Prof. John M. Maisch in the American Journal of Pharmacy for February, 1874.

Cangai: *Relbunium hirtum*, Schumacher. An herb found in abundance in the Argentine Republic, where it is used in the treatment of acute rheumatism.

## COMPOSITÆ.

*Eupatorium Ayapana*, Ventenat. This very aromatic Brazilian composite has a coumarin-like odor, with a slightly bitter and astringent taste. L'Heritier and Martius report that it is used in Brazil as an antidote for snake bites, both internally and as an external fomentation. The leaves are also recommended for indigestion, pectoral affections, and cholera. They appear to have been used in Europe for similar purposes in the early part of the present century. (Am. Journ. Pharm., Mar., 1877.)

*Guaco*.—Robert B. White, of Salada, New Grenada, claims that *Mikania Guaco* furnishes the guaco of commerce. Other observers insist that the true origin of guaco has not yet been definitely determined, as quite a number of species of *Mikania*, *Eupatorium*, and *Aristolochia* are indifferently known as guaco in Mexico and Central America. The root is regarded as a specific in rheumatic affections in Mexico, a fluid extract of it being used both internally and externally. The pain and stiffness are said to be often relieved by a single application of the preparation, provided that the parts are kept well covered with it all night. Mr. Robert B. White, who has lived in Choco and other snake-infested regions for many years, testifies that guaco leaves, properly and promptly administered, are a cure for the bites of the most venomous serpents of that country. (Pharm. Journ. Trans., Nov., 1880.)

Topas aire (botanical name not known) is used in the Argentine Republic in the treatment of ophthalmia.

Nio, probably identical with mio-mio, from *Baccharis cordifolia*, Lam. This shrub is a deadly poison to cattle. According to P. N. Arata, it contains an alkaloid, baccarine. The plant is indigenous to the Argentine Republic. (Zeitschr. d. Oestr. Apoth.-Ver., 1881, No. 27.)

Raiz del Pipitzahuac: *Perezia Dugesii*. The root of this plant has been used for a long time in northern Mexico as a powerful laxative. This action was found by Prof. Rio de la Liza to be due to a peculiar acid, which he named pipitzahoic acid. Dr. Weld determined its ultimate composition to be  $C_{30}H_{20}O_6$ . The same acid has also been obtained from *Perezia Wrightii*, Gr., and from *Perezia nana*, Gr. (Am. Journ. Phar., Apr., 1884.)

*Parthenium hysterophorus* is much esteemed in the Antilles as a substitute for quinine. It is found in waste places throughout tropical and subtropical America. It is characterized by extreme bitterness, due to the presence of a glucoside, which has been called "parthenine." Dr. Torar has found the drug to be decidedly efficacious for neuralgia, both intermittent and non-intermittent, especially for the cranial form, but to be utterly without effect as an antipyretic. (Gaz. Médic., May 29, 1886.)

*Mutisia viciæfolia*, Cavanilles. Dr. Saco, of Bolivia, reports this plant to enjoy the reputation of curing phthisis and all pulmonary diseases. The plant is indigenous to the western part of South America from Chile to Peru. It belongs to the labiatifloral compositæ, which are confined chiefly to South America. (Journ. d'Hygiène, 1886.)

*Haplopappus Baylahuen*, C. Gay. Used in the province of Coquimbo as an anti-hysterical remedy, and in veterinary practice in the treatment of wounds. The plant has been found to contain a volatile oil, a fatty oil having the odor of the plant, a brown resin of sharp taste, and tannin. The taste of the drug is said to resemble that of pichi. (Drug. Bull., 1890.)

Zinco or Chinchilla: *Tagetes glandulifera*, Schrk. A native of the Argentine Republic, but not found very plentifully there. It is reputed to have tonic properties.

Carqueza: *Baccharis articulata*. Found abundantly in the same country. Said to be useful for indigestion, sterility, etc.

Yerba mercurial: *Senecio albicaulis*. Also an Argentine herb. It possesses the properties of an alterative, diaphoretic, febrifuge, and expectorant.

## LOBELIACEÆ.

Vegetable Kermes: *Lobelia Delisseana*. Dr. Crescentio Garcia claims the therapeutic virtues of this Mexican lobelia to be superior to those of the *Lobelia inflata*. The name of vegetable kermes has been bestowed upon it on account of a fancied similarity in its action to that of antimony. It has been used for twenty years by several practitioners of Guadalajara in the form of tincture. Excellent results have been obtained from its employment in nervous affections of the chest, and in severe cough and asthma. Dr. Garcia has himself used it with great success in bronchitis, asthma, whooping cough, and particularly in pneumonia. The root is without odor, but when pulverized it is sternutatory. When chewed it is at first sweetish, but this soon changes to a bitter sickly taste. (*La Voz de Hipocrates*, Apr., 1886.)

## ERICACEÆ.

Manzanita: *Arctostaphylos tomentosa*, or *A. glauca*, Lindl. The fruit of this shrub, which is produced in clusters, resembles a small apple, whence the name from manzana, the Spanish word for apple. It has an agreeable taste, and is therefore largely consumed by the Mexicans and Indians, both in the ripe and in the unripe state. Manzanita leaves are regarded as an astringent tonic, with special action on the urinary organs. They have been highly recommended in the treatment of gleet, vesical catarrh, incontinence of urine, etc. Dr. H. W. Rand thinks that these leaves may be advantageously used during the stationary or decreasing stage of gonorrhœa and in long-standing gleet, when the older drugs have failed or have disturbed the stomach. (*Parke, Davis & Co.'s Brochure*, No. 44.)

## PLUMBAGINEÆ.

*Guaycuru*.—The root of *Statice Brasiliensis*, Boissier. Found in the Argentine Republic. Baycuru root is sometimes confounded with it, but, according to E. M. Holmes, the latter is derived from an entirely different plant, which has not yet been identified. The natives have unlimited faith in the astringent and absorbent virtues of both of these roots, which they employ freely in the form of fomentation or vapor for all kinds of glandular swellings and enlargements. Dr. Landul has sometimes found the drug to fail utterly, but as a rule he believes it to be reliable, both externally and internally, and to be particularly valuable as a gargle. The taste of the drug is astringent, slightly salty, and fishy. (Dr. Charles Symes, in *Pharm. Journ. and Trans.*)

## SAPOTACEÆ.

*Lucuma littoralis*, Mart. The fruit of this Brazilian plant has a sweetish, unpleasant, and astringent taste. Dr. Peckolt states that in Brazil it is used as a remedy for chronic diarrhœa.

*Lucuma mammosa*, Gärtner. Also found in Brazil. The fruit is eaten as a dessert, a little lemon juice being added to correct its insipidity. The seeds, which contain 25 per cent of a bland, fixed oil of pleasant flavor and odor, are used in kidney complaints. The bitter bark is used in intermittent fever in teaspoonful doses of a 20 per cent tincture.

*Lucuma obovata*, H. B. Kth. The fruit of this Brazilian species has a very pleasant, creamy taste. The seeds are roasted and used as a beverage. The decoction and emulsion of the raw seeds are used in the treatment of catarrh of the bladder.

*Lucuma rivivoca*, Gärtner. This fruit has a mucilaginous, agreeable, sweetish pulp, and constitutes a popular dessert. It is used medicinally in the form of confection and syrup in the treatment of dysentery and catarrh of the lung. The emulsion of the seeds is a popular diuretic.

*Lucuma torta*, Mart. A syrup is made from the edible fruit, which is used in bronchitis, catarrh, and affections of the lungs.

*Lucuma psammophila*, A. D. C. The agreeable, sweet fruit is regarded as a delicacy, and is used in the preparation of a confection. The bark enjoys the reputation of being a tonic.

*Lucuma glycyphlœa*, Mart. et Eichl. This may be viewed as the most important of the group, as it is the source of the commercial extract introduced from Brazil under the name of monesia. The bark of this tree was imported into Europe as early as 1555, and it is the part which is now principally exported. Dr. Peckolt has succeeded in crystallizing monesin from it. (Pharm. Rundschau, Jan. and Feb., 1888.)

## APOCYNACEÆ.

*Thevetia neriifolia*. Indigenous to the West Indies, New Granada, and Peru. The bark and the seeds of this tree are regarded as a powerful febrifuge. According to De Ury, the seeds contain 75 per cent of an almost colorless fixed oil, and a crystallizable glucoside, thevetine, which can be split up into glucose and thevetresin. (Journ. de Ph. et Chim., Mai, 1869.)

*Thevetia yccotti*, D. C. Joyote. Found in the damp, hot regions of the fertile mountains of the great Mexican Cordillera. The Aztecs believed the seeds to cure the bite of the rattlesnake. The ancient Mexicans made use of the milky juice of the tree for curing deafness and cutaneous eruptions. They applied the leaves topically for toothache and as an emollient and resolvent to tumors. The fruit was used by them for healing ulcers. At present the fruit is called in Mexico "huesos ò codos de fraile," bones or friar's elbow, from its resemblance to the human elbow. The seeds have a high reputation among the people in hæmorrhoids. They are first triturated, then mixed with suet, and applied locally. Prof. Alfonso Herrera obtained a well-defined glucoside from the seeds, which he named thevetosin. Physiological experiments made by Luis Hidalgo Carpia with thevetosin proved it to be very venomous, acting as a powerful emetic and paralyzing the respiratory organs, and possibly also the general muscular system. (Am. Journ. Pharm., Apr., 1877.)

Pao-Pereira: *Geissospermum laeve*, Bouillon; *Picramnia ciliata*, *Vallesia punctata*, *Tabernæmontana lævis*, *Geissospermum vellosii*. A tree native to Brazil. An alkaloid was discovered in it in 1838 by Santos, and named pereirine. About 1830 Prof. Silva made known the febrifuge and antiperiodic properties of the bark. The alkaloid, which is now sometimes called geissospermum, is used in Brazil in an impure form. It occurs there as a brownish yellow, amorphous mass of extremely bitter taste. (Compt. Rend.)

*Quebracho*.—The bark of *Aspidosperma quebracho-blanco*, Schlecht. An ever-green tree, 14 to 20 meters high, growing in the Argentine Republic, in northeastern Bolivia, northern Patagonia, and southwestern Brazil. The same name seems to be also applied to *Quebrachio morongii*, Britton, *N. O. Terebinthaceæ*, which is known to the natives as quebracho colorado, and is used largely for tanning purposes. Quebracho has been introduced as a sovereign remedy in dyspnoea. It relieves the cyanosis and the sense of suffocation due to embarrassed respiration, as in emphysema, capillary bronchitis, phthisis, and chronic pneumonic processes, and in asthma. It appears to assist in the oxygenation of the blood, and at the same time to stimulate the respiratory centers. Quebracho bark is said to contain at least six different alkaloids, the most important of these being aspidospermine, quebrachine, hypoquebrachine, and aspidosamine. The com-

mercial aspidospermine seems to be a mixture of all of the six alkaloids, so that it fairly well represents the activity of the drug. It is probably the most valuable remedy known for dyspnœa in its various forms. The dose of it is given at one-fourth to one-half grain. The crude drug and its corresponding fluid extract have of late become sufficiently popular to warrant their recognition by the new United States pharmacopœia of 1890, which has bestowed the official title of aspidosperma upon the remedy.

Guachamaca: *Malonetia nitida*. According to Dr. Schiffer, an aqueous extract of this Venezuelan plant is reputed to have wonderful effects in allaying convulsions of the motor apparatus. It contains an alkaloid, guachamacine, soluble in water, which in its physiological action resembles curarine. Dr. Schiffer believes that this remedy may be found to be valuable in diseases involving an exaggerated action in the motor apparatus, and possibly also as a general hypnotic. (New Rem., Aug., 1882, 231.)

Yalapa: *Echites longiflora*. A plant of the Argentine Republic, where it is used as a purgative. In the powdered form it is also employed in plasters. (Amer. Drugg., Nov., 1889.)

#### ASCLEPIADACEÆ.

Condurango: *Gonolobus condurango*, Triana. In 1871 the Government of Ecuador forwarded some of this drug to the State Department at Washington, with a request that it be analyzed and tested as to its medicinal value. The parcel was accompanied by testimonials of Drs. Cæsares and Eguiguren, of the Province of Loja, attributing great medicinal virtues to the drug in the treatment of cancer fungus hæmatodes, and constitutional syphilis. The drug was subsequently introduced into this country in a manner calculated to prejudice the medical profession against it, so that there has been a disinclination here to give it a fair trial. It has been much more carefully and persistently experimented with in Germany, where numerous reports on it have been published. Dr. Wilhelmy, in the Berl. Klin. Wochenschrift, claims that the pains of patients having cancer of the stomach became materially reduced by the use of condurango. The appetite was improved, the painful vomiting was diminished, and an increase of weight took place. Though all of his patients died except one, he concludes that the drug afforded them material relief, and he feels encouraged to make further trials with it. Condurango was even made official in the second edition of the Pharmacopœia Germanica. A most exhaustive treatise on the therapeutic action of condurango has been published by Dr. L. Riess, in the Berl. Klin. Wochensch., No. 10, 1887. It has been translated and published in Parke, Davis & Co.'s Brochure No. 18.

#### CONVOLVULACEÆ.

*Cabello de Ángel, Icipo Chumb.*—A species of *Cuscuta* or dodder, a parasitical plant of the Argentine Republic. It is regarded there as a gentle laxative, diuretic, and antiphlogistic. It is used in the form of an infusion for intermittent fevers and for congestion of the respiratory organs. Also, as a decoction in cases of hæmoptysis, inflammation of the throat, and for internal abscesses. The plant is somewhat rare in its native country. (Brit. and Colon. Drugg.)

#### SOLANACEÆ.

Braço de Preguiça, or Velame: *Solanum jubatum*, Dunal. A Brazilian drug, consisting of large, brittle leaves of papery texture, about a foot long by 9 inches wide. Dr. Barnsley states that the leaves and root of this plant are used as anti-syphilitics in the form of infusion or extract. According to Martius, the drug is used as a resolvent in congestion of the bowels, and as an external application for cleansing and healing wounds and ulcers. (Ph. Journ. Trans., May 15, 1875.)

Duraznillo: *Cestrum pseudoguina*, Mart. The leaves and root bark are employed in fevers and abdominal complaints in the Argentine Republic.

Pichi: *Fabiana imbricata*, R. et P. Indigenous to Chile. A plant with plume-like sprays of light, bluish-green color, growing on high, dry hilltops. Its appearance resembles that of a conifer very much more than that of a solanaceous plant. Its medical properties are diuretic, terebinthinate, and tonic. Pichi is very highly recommended in acute or chronic vesical catarrh, when following a mechanical cause, such as gravel or a uric-acid diathesis. It seems to induce the expulsion of the gravel and of those calculi that can be passed through the urethra, and to modify or cure chronic purulent secretions. It is also useful in icterus, dropsy, and dyspepsia due to biliary secretions, but it is contra-indicated where there is organic kidney disease. The fluid extract of pichi is given in doses of 10 to 40 minims, the solid extract in doses of 2 to 10 grains. Dr. Lyons announced a bitter alkaloid of pichi which he named "fabianine." Messrs. Nivière and Liotard were unable to find any trace of such an alkaloid. They attribute the therapeutic effects to a crystalline, fluorescent glucoside, and this statement has since been confirmed by Messrs. Trimble and Schroeter. Pichi is one of the most important of the new drugs secured by Dr. H. H. Rusby in his South American explorations. A very full report on the literature of this valuable drug has been published by Parke, Davis & Co. in their Brochure No. 49. The plant is also illustrated in the Proceedings of the American Pharmaceutical Association for 1886, page 395.

Manaca, Mercurio vegetal: *Brunfelsia Hopeana*, Benth.; *Franciscea uniflora*, Pohl. Indigenous to Brazil and the greater portion of equatorial America. The Brazilian Indians use manaca for rheumatism and syphilis, taking the scraped root bark in half a tumblerful of rum. Manaca may be regarded as a powerful alterative, valuable as an antisyphilitic, antiarthritic purgative, and diuretic. The fluid extract is given in doses of 10 to 60 minims. Prof. G. Dragendorff, of the Imperial University at Dorpat in Russia, has discovered a very energetic alkaloid in manaca. A number of highly interesting reports on the chemical composition, natural history, physiological action and therapeutic properties of manaca have been collated and published in Parke, Davis & Co's. Brochure No. 44. The plant has sometimes been classified among the *Scrophulariaceæ*.

#### OROBANCHACEÆ.

*Crescentia Cuyete*, L. The fruit of this plant is used extensively by the Indians of tropical South America. The pulp is valued medicinally as a laxative. Mr. Gustav Peckolt prepared an alcoholic extract of it, which he found to be effective as a gentle laxative in doses of a decigram, while half a gram produced a decidedly drastic effect, without, however, causing pain or inconvenience. The pulp, boiled with water until a black, pasty mass is produced, is applied in the form of a plaster for erysipelas. (Pharm. Rundschau, Aug., 1884.)

#### GESNERIACEÆ.

*Martinia montevidensis*, Cham. The seeds of this plant are used in the Argentine Republic for diseases of the eye. (Am. Journ. Pharm., March, 1882.)

#### BIGNONIACEÆ.

Ipé assú, Paú semto: *Tecomia Ipé*, Mart. Indigenous to some of the Brazilian provinces. A decoction of the wood is used in the treatment of the various forms of scabies. A decoction of the bark is employed both internally and externally in the treatment of herpetic affections and as a gargle for angina tonsillaris. The juice and infusion of the leaves are made use of in various ophthalmic affections. As the wood is often substituted for guaiacum, it was examined chemically by

Dr. Th. Peckolt, who found it to contain a large percentage of chrysophanic acid. (Zeitschr. d. Oestr. Apoth.-Ver., 1873, p. 549.)

*Caroba.* The leaves of *Jacaranda procera*, Sprengel. A plant indigenous to Brazil. Caroba leaves are inodorous, but they have a bitter and astringent taste. It is claimed for them that they possess alterative, diuretic, sudorific, and tonic properties to a marked degree, on account of which they have great value in the treatment of syphilis in all its forms. When there is much pain in the limbs it is advised to combine potassium iodide with them. In old syphilitic ulcers caroba leaves are recommended topically as well as internally. Their use has also been suggested in other obstinate cutaneous affections. The fluid extract of the leaves is an eligible preparation, which may be given in doses of one-fourth to 1 fluid-dram. Dr. Ottokar Alt, of Hamburg, fully confirms the value of this drug for old syphilitic eruptions. Camillo Weber, during sixteen years' residence in Brazil and other parts of South America, has seen the caroba leaves employed frequently by the resident physicians in the treatment of syphilis, and with the happiest results. Dr. Peckolt claims to have extracted an alkaloid from the leaves, which he names carobine. This also has been found to be efficacious in syphilitic and scrofulous affections. (Parke, Davis & Co.'s Brochure No. 11.)

*Jacaranda lancifolia.*—A plant from the United States of Colombia which has been experimented with by Drs. Murray Smith, Alfred Wright, and Z. Mennell. The leaves were found to be very useful in cases of gonorrhœa, syphilis, and in vesical affections attended with purulent urine. Prof. John M. Maisch, however, believes the plant to be identical with the *Jacaranda procera* noted above.

Cinco folhas: *Sparattosperma Leucantha*, Mart. Dr. Theodor Peckolt advocates the introduction of the leaves of this handsome, tall Brazilian tree into European medicine. The leaves of the sparattosperma have powerful diuretic properties; they are also extensively used for diseases of the spleen and liver. They are administered in the form of infusion, tincture, or alcoholic extract. Dr. Peckolt has obtained from them 2.8 per cent of sparattospermin, which was found to be a neutral substance and not a glucoside. In its composition it approached very closely to phloridzin. Dr. Peckolt found it to be a diuretic in doses of 1 to 2 grains. (Zeistchr. d. Oestr. Apothek.-Ver., Aug. 10, 1878.)

#### VERBENACEÆ.

*Lippia Mexicana.*—The plant is indigenous to moist places in southern Mexico. The leaves have an agreeable taste, which has been compared to that of the lemon balm. Other observers call the odor pungent, and are reminded by it of pennyroyal and camphor. Dr. Podwissotzki, of Dorpat, Russia, has examined the leaves and has obtained from them tannin, a volatile oil, and a camphor-like body, which he named lippiol. Prof. John M. Maisch is of the opinion that Dr. Podwissotzki's researches have reference to the *Cedronella Mexicana*, Benthams, which has been admitted into the Mexican pharmacopœia under the name of toronjil. The constituents of *Lippia Mexicana* are free from toxic properties. The therapeutic virtues have been studied by Saxton, Durant, Blasdale, and Blackerby. The drug appears to be a good expectorant, useful for reducing the irritable condition of the mucous membranes of the organs of respiration. It has rendered excellent service in acute and chronic bronchitis, and in bronchial affections complicated by serious irritation. (Parke, Davis & Co.'s Working Bulletin on the Drug.)

*Lippia graveolens*, Kauth, and *Lippia dulcis*, Treviranus, called in Mexico "yerba dulce." These are there used in the form of infusion for their demulcent, pectoral, and emmenagogue properties. The yerba dulce has been subjected to a proximate analysis by Rio de la Loza. (Amer. Journ. Pharm., 1885, p. 330.)

Yerbon o Menstruz: *Stachytarpha dichotoma*. Used by the natives of the Argentine Republic as a tonic, and in bronchitis, coughs, convulsions, colic, paralysis, contusions, etc. (British and Colon. Druggist.)

## LABIATÆ.

Yerba buena: *Micromeria Douglasii*, Berth. Found on the Pacific coast of North America. This has long been a favorite medicine among the Mexican population. It is a grateful aromatic stimulant, and is useful as a carminative and anthelmintic. It allays nausea and spasmodic pains of the stomach and bowels, and reduces the force and frequency of the pulse. Yerba buena is also an excellent anthelmintic, well adapted for the expulsion of round worms from children. The dose of the fluid extract is from one-half to two fluid drams. When freshly gathered the herb has a grateful perfume, peculiarly sweet and aromatic. When dry its strong scent recalls that of a mixture of peppermint and camphor; by others its odor is compared to that of pennyroyal. When chewed it excites a moderate flow of saliva, which it tinges to a deep-green color. It produces an aromatic, pungent, slightly bitter, and camphoraceous taste in the mouth. Dr. E. Palmer states that the Western Indians use a tea prepared from it for fevers and colds. (Amer. Journ. Pharm., Dec., 1878; Parke, Davis & Co.'s Brochure No. 58.)

Albochaca: *Ocimum basilicum*. The fresh juice of this labiate is used as an efficient anthelmintic in Buenos Ayres. Worms in every stage of their development rapidly leave their location after the juice reaches them. No injury results from the administration of the juice, whether worms are present or not, the medicine acting as a laxative and disinfectant. Fifty grams of the juice are given, followed in two hours by a dose of castor oil. If any worms were present there is soon a free discharge of them. (Gaillard's Med. Journ., Mar., 1880.)

Chia: *Salvia chian*, La Llave; *Salvia Hispanica*. This labiate is met with very abundantly in the northern States of Mexico. The seeds abound in mucilage and fixed oil, being in this respect similar to flaxseed. They are highly valued for the preparation of a refreshing drink for the sick. This is made by macerating a tablespoonful of the seeds in a tumblerful of cold water for half an hour, then sweetening and flavoring it with orange-flower water. This drink is very efficient in fevers, when great thirst usually distresses the patient. As a demulcent and emollient the seeds are superior to flaxseed. The mucilage prepared from them is often used advantageously as a vehicle for mild injections in the earlier stages of venereal diseases. It is also very useful as a gargle and wash in throat affections. Chia seeds are small in size, about one-sixteenth of an inch in length and one twenty-fourth of an inch in width. They are oblong-ovate, somewhat flattish, smooth, and glossy. When immersed in water they readily yield their mucilage to it, swelling to about twice their natural size. They are inodorous when whole, but when crushed they have an oily smell similar to that of ground flaxseed. *Salvia chian* is quoted in the Farmacopea Mexicana as a new species. Dr. Edward Palmer claims that *Salvia Columbaria*, Benth. is the "chia" of the Mexicans and Indians of Arizona and New Mexico. Prof. John M. Maisch concludes that at least several species of *Salvia* have fruits resembling very small ricinus seeds, and that the generic name of chia is indiscriminately applied to all the fruits of salvias that have mucilaginous characters. (Amer. Journ. Pharm., May, 1882.)

*Ovechá-caá*—The common people of the Argentine Republic apply this title to several species of Hytis, which are there met with rather frequently, and which are used in the treatment of syphilis. (Brit. and Colon. Drugg.)

## CHENOPODIACEÆ.

*Chenopodium quinoa*—The seeds of this plant contain nearly 40 per cent of starch. They have been used for many years as an article of food in Chile and Peru. Mr. M. C. Cooke describes a bitter seeded variety, known locally as "amargo," which is there cultivated in gardens and used medicinally. These

seeds are applied to sores and burns in the form of decoction or cataplasm. They are also given internally as a substitute for quinine. Their bitterness seems to be confined to the husks, or testa of the seeds. It may be removed by digestion in dilute solution of sodium carbonate, and subsequent washing. (Am. Journ. Pharm., 1872, p. 557.)

Herba Santa Maria of Brazil is the familiar *Chenopodium ambrosioides*, L., where it is also known under the names of matruz, mentruz, and mastruco, although these same terms are occasionally bestowed also on several other plants. The tops of the herb are employed in Brazil as an efficient vermifuge, when made into an electuary with castor oil. (Ph. J. Trans., Mar., 1879.)

Yerba de Santa Maria, or Caané, are the popular names in the Argentine Republic for the *Chenopodium anthelminticum*. It is there used for hysterical fits, indigestion, catarrh of the stomach, dysentery, pleurisy, asthma, and particularly for paralysis of the tongue. (Amer. Drugg., Nov., 1889.)

#### PHYTOLACCACEÆ.

Pipi root: *Petiveria hexaglochin*, Fischer. The genus is confined to tropical America. Richard refers pipi root to *Petiveria alliacea*, Linn., and Martius to *Petiveria tetrandra*, Gomez. Pipi root attracted attention in Europe about sixty five years ago, and its investigation has lately been resuscitated. The root is recommended as an emmenagogue. It has also been used internally and in fomentations as a diaphoretic, stimulant, expectorant, anthelmintic, and in fevers, toothache, and gonorrhœa. (Am. Journ. Pharm., Aug., 1887.)

Guiné ò pipi is the name applied in the Argentine Republic to the *Petiveria alliacea*, where the root is used as a febrifuge and in the treatment of rheumatism, hydrophobia, snake-bites, etc. (British and Colon. Drugg.)

#### POLYGONACEÆ.

Raiz del Indico: *Rumex hymenosepalum*, Torrey. A name applied by the natives of Mexico to a plant growing abundantly along the Rio Grande, the root of which is used by them as an astringent. Several of these fleshy and fusiform roots grow together from a short head. They are nearly circular, 1 or 2 inches in diameter and from 2 to 6 inches long. On chemical examination they were found to contain chrysophanic acid, aporetin, phæoretin, and several non-important principles, with about 23 per cent of tannin. Prof. Henry Trimble reports more recently that this root is now largely used in tanning, under the name of canaigre, on account of the large proportion of tannic acid which it contains. (Amer. Journ. of Pharm., Feb., 1876, and Aug., 1889.)

#### ARISTOLOCHIACEÆ.

Milhomen, Jarra, Jarrinha: *Aristolochia cymbifera*, Mart. This Brazilian root consists of pieces about 4 inches long, having a camphoraceous taste resembling that of serpentaria, and also a bitter, pungent taste. The medical properties are analogous to those of serpentaria. This root has been repeatedly tried in Europe during the last century, and has lately again appeared in the European drug markets. It does not appear to be superior to other well-known remedies of similar character. (Chem. Zeit., 1887, 379.)

#### PIPERACEÆ.

Yatebû-caá, the common name of several species of peperomia, which are met with in abundance in the Argentine Republic, where they are used as febrifuges and tonics. (Brit. and Colon. Drugg.)

Yerba mansa, or yerba del manza (mild herb): *Houttuynia Californica*, B. & H.; *Anemopsis Californica*, Hooker; *Anemia Californica*, Nutt. An herb indigenous to California and northern Mexico, where it is used as a stimulant and tonic. The natives employ it in malarial fevers, particularly in the chronic forms. In diarrhoea and dysentery it is a remedy of pronounced value. The fluid extract is given in doses of 15 to 60 minims. The general appearance of the growing plant is very much like that of the common plantain, but the leaves are smaller and more prostrate. It presents indeed so handsome an appearance that it has been recommended for ornamental purposes. Dr. H. H. Rusby relates that the natives and settlers whom he met with in his travels extolled the drug as an excellent stomachic, and that they also attributed alterative and anti-rheumatic properties to it. Occasionally they used the plant as a stimulating application to open wounds and to swellings. Prof. J. T. Rothrock regards it as a diuretic and as being of service in the form of baths for rheumatic affections. He looks upon it as a promising plant for future investigation, and he anticipates that in a general way it will be found to be similar to the ava kava root in its therapeutic effects. Dr. George states that the native Spanish population look upon yerba mansa as a panacea. In his vicinity it is used in gonorrhoea and in the same classes of urinary difficulties in which cubebs are available. As an anti-emetic he administered one or two drops of the fluid extract in a teaspoonful of water with good effect. It is stated that the knowledge of the remedial virtues of this plant was preserved as a secret of great value by the natives for a very long time. Mr. J. U. Lloyd obtained a large proportion of a volatile oil from the drug, to the presence of which he attributes its strong piperaceous odor and taste. (Parke, Davis & Co.'s Brochure No. 58; Am. Journ. of Pharm., Jan., 1880.)

*Jambu assu*.—The root of *Piper jaborandi*, Vell.; *Serronia jaborandi*, Gandie et Guillemm; *Ottonia anisatum*, Spreng.; *Ottonia jaborandi*, Kunth. This plant is called "jaborandi," in common with many others which are employed in popular medicine, as sudorifics, diuretics, and febrifuges in Brazil, where it is indigenous. Jambu assu is believed to have a specific action on the uterus, and it is employed for the relief of painful affections of that organ. The opinion seems to prevail that in sufficient dose the drug is capable of inducing abortion. (Parke, Davis & Co.'s Brochure No. 36.)

## LAURACEÆ.

*Laurel blanco*, or *Canela molle*.—The leaves of the *Ocotea* (*Strychnodaphne suaveolens*, indigenous to the Argentine Republic, are recommended for their diuretic, carminative and emmenagogue properties. (Amer. Drugg., Nov., 1889.)

## EUPHORBIACEÆ.

*Anda-assu*, *Indayuçu*, *Fructu da Amara*, *Purga de Gentio*.—The fixed oil, expressed from the seeds of the *Anda Brasiliensis*, Radde; *Johannesia princeps*, Velloz. This tree is indigenous to Brazil. When its bark is incised a milky juice exudes, which is used for poisoning or stupefying fish. The fruit is over 3 inches in diameter, and contains about 50 seeds. A clear, reddish, fixed oil is obtained from them by expression. Dr. Norris has tried this at the Pennsylvania Hospital, and he found it to be a prompt purgative in doses of 50 minims. It produces neither nausea, vomiting, nor irritation of the stomach or intestines. Compared with castor oil, it is equally active in smaller doses, it is more liquid, and it is free from the disagreeable odor of the latter (Am. Journ. Pharm., Oct., 1881.)

*Alveloz*.—The milky juice of the *Euphorbia heterodoxa*, Müll., indigenous to Brazil. It was sent by the American consul at Pernambuco to the State Department at Washington with the statement that several cases of cancer had been healed by its external application. A portion of the drug was given by the Sur

geon-General to Dr. Smith Townsend for trial in a case of lupus of the nose of nearly forty years' standing. The ulcer, which had resisted all previous treatment, was healed in a few days by the application of alveloz. The action of the juice is irritating, causing local inflammation. It exhibits the combined action of a caustic and of papine. In cancrioid ulceration it promptly destroys the affected tissues layer by layer. A profuse suppuration follows its application to a granular surface. Dr. Clement Ferreire, of Rezende, Brazil, thinks it is destined to play a considerable rôle in the therapeutics of cancrioid and syphilitic ulcers. (Proceed. of the Amer. Pharmac. Associat., 1885; Parke, Davis & Co.'s Brochure No. 3.)

*Euphorbia pilulifera*, Linn.—This plant has long been used in tropical countries in the treatment of asthma, bronchitis, and cardiac dyspnoea. The dose of the fluid extract is from 30 to 50 minims. The drug has been analyzed by Charles G. Levison, Ph. G., of San Francisco, Cal. Dr. C. C. Baker, of New Mexico, has used the plant in two cases of asthma with prompt and satisfactory results. As far as he was able to judge from the sensible effects, however, the virtues of the plant are probably not superior to those of the closely allied indigenous weeds, *Euphorbia maculata* and *Euphorbia hypericifolia*. (Therap. Gazette, Jan., 1884.)

*Pallillo. Croton morifolius*.—This Mexican plant has been experimented with in France by Messrs. Dugees and Armendaris. Two or three drops of the oil expressed from the seeds acted similarly to a moderate dose of castor oil. The Mexicans use an infusion of the leaves of this plant as a remedy for gastralgia and atony of the stomach. The tincture is of benefit in facial neuralgia, either used as a liniment or dropped into the ear, or taken in 10 to 15 drop doses with orange flower water. (Am. Journ. Pharm., 1884, 476.)

Velamen: *Julocroton Montevidensis*, Klotz. An herb somewhat rare in the Argentine Republic, where it is prescribed in cases of syphilis and syphilitic rheumatism. (Amer. Drugg., Nov., 1889.)

*Jatropha macrorhiza*, Benth. A Mexican plant, said to resemble podophyllum in its action. Dr. A. H. Noon, of Oro Blanco, Pima County, Ariz., recommends it as a new hydragogue cathartic, with cholagogue and other properties worthy of investigation by the medical profession. (Med. World, Oct. 1889, p. 421.)

*Balsamo*.—The latex obtained by incisions into the *Jatropha multifida*. This is a popular vulnerary employed in Brazil for wounds. An infusion of the seeds of this Brazilian plant, or the fixed oil obtained from them, is used as a purgative. The dose of the oil is 10 to 15 drops. (Rev. Pharm. de Rio de Janeiro, 1886.)

#### URTICACEÆ.

*Celtis Tala*, Gill. A tree found in the Argentine Republic. In infusion is used there in pectoral catarrhs. (Zeitschr. d. oestr. Apoth. Ver., 1881.)

#### PALMACEÆ.

Carnaüba root, Carnahuba: *Copernicia cerifera*, Martius; *Corypha cerifera*, Arruda da Camara. This species of fan palm is indigenous to Brazil and Peru. It is also met with as far south in Paraguay, La Plata, and Chile as the thirty-first degree of latitude. The tree is illustrated in the proceedings of the American Pharmaceutical Association for 1878. The natives of the extensive plateaus in the northern provinces of Brazil derive from this palm nearly all their means of subsistence and comfort. The wood, leaves, leaf fibres, leaf stalks, fruit, terminal leaf-buds, and the hollow stems are all of them used for numerous domestic purposes. The roasted fruit kernels furnish an agreeable beverage, known as café de carnaüba. The most valuable product of all is the carnaüba, or palm wax, which has become an important article of commerce. The root of this palm enjoys a high reputation in its habitat as an efficient alterative and diuretic. Possibly it may at

some time in the future become equally popular with sarsaparilla, stillingia, etc. Lescher's "Recent Materia Medica," 1888, mentions carnauba root as an alterative and diuretic, used as sarsaparilla in decoction of 1 part to 16, in doses of an ounce. (Parke, Davis & Co.'s Brochure No. 11.)

*Oleo de Subati*.—The fixed oil prepared from the pulp of the fruit of the *Raphia vinifera*, Beauv., var. *toedigera*, Mart., a magnificent palm flourishing in the moist lowlands of equatorial Brazil. Dr. Theodor Peckolt states that this oil has a reddish yellow color and a bitter taste. It is used internally as a tonic and externally as a lubricant for sprains, etc. (Pharm. Rundschau, June, 1888.)

## BROMELIACEÆ.

*Agave Americana*.—The discovery of the juice of the "maguey" plant as an intoxicating beverage is dated as far back as 1045 to 1050, under the reign of the eighth king of the Toltec tribe. The diverse properties of the plant were certainly known many years before the discovery of Mexico by the Spaniards. The juice of the plant, or pulque, is consumed in enormous quantities, 50,000 bottles of it being annually introduced into the City of Mexico alone. It has been successfully used in the U. S. Army on the Mexican frontier for the prevention of scurvy. F. M. Murray claims that the plant which furnishes the pulque is distinct from the *Agave Americana*, and that it is properly named *Agave Mexicana*. The juice is said to have laxative, diuretic, and emmenagogue properties. (Am. Journ. Pharm., July, 1867.)

## SCITAMINEÆ.

Banana root: *Musa sapientum*, Linn.; *Musa paradisiaca*, Linn. Indigenous to the tropics of both hemispheres. The root of the familiar banana is recommended by Dr. F. Frankenstein, of Hillsboro, Kans., as a remedy in bronchocele. (Parke, Davis & Co.'s Brochure, No. 6.)

## CYPERACEÆ.

Espartillo: *Scirpus capillaris* is of frequent occurrence in the Argentine Republic, where it is employed in pulmonary affections.

## EQUISETACEÆ.

*Cola de Caballo*.—A rare species of *Equisetum*, indigenous to the Argentine Republic. It has diuretic and astringent properties, and is used in its habitat in the treatment of gonorrhœa and diarrhœa. (Brit. and Colon., Drugg.)

## DISCUSSION.

Dr. RUSBY. Dr. Miller is deserving of the special gratitude of the section for taking up this important subject, even though the conditions of our present knowledge preclude even comparative completeness. The following points were noted in passing: Coto: It has been established that Dr. Schuchardt was in error in referring coto to a variety of *Drimys Winteri*. A number of barks of Bolivia are called by this name. I have recently myself received one new one, and four others are on their way. Boldo: I have evidence of the existence of a second variety of this drug, having seen a twig with leaves, evidently a species of *Peumus*, but not *P. Boldo*. *Violaceæ*: Only one medical plant was mentioned as belonging to this family, whereas it is very rich in them, ipecac-like properties being predominant. A drug which should not be passed by is the bark of several species of *Bocconia*, arborescent plants in the *Papaveraceæ*, yielding an abundant sanguinarine like

alkaloid. Jaborandi: Of the two varieties noted, the Rio is very inferior to the Pernambuco, but the latter is not yet in abundant or steady enough supply to specify it solely in the United States pharmacopœia. Rhatany: The drug now sold for *Savanilla Rhatany* is not genuine. It is a Rhatany, but not the old Savanilla. Baccharis: There is another species than the Mio-Mio, which yields an alkaloid, very bitter, and which acts as an anthelmintic.

---

### THE PHARMACOPŒIA AND ITS STUDY.

By ROBERT W. GREENLEAF, A. M., M. D., of Boston, Mass.,

*Professor of Materia Medica and Botany, Massachusetts College of Pharmacy ; Physician, Boston Dispensary.*

Pharmacology, in common with other departments of medicine, is in a transitory stage. We must recognize that a new era is arising in the treatment of disease, coincident with the advance in knowledge, especially in the department of histology and pathology. Certain members of our profession, carried away by their studies in bacteriology, have been tempted to forget that drugs and their preparations still have a place in the armamentarium of the practicing physician. On the other hand, gentlemen trained in the encyclopedic methods of the past find it difficult to realize that many of their treasures from the animal, the vegetable, and the mineral kingdom are fit only for the departments of some museum devoted to the history of medicine. Between these extremes the pharmacology of to-day desires to take its stand. It desires to equip the physician, whose specialty it is to administer at the bedside of the sick, with a proper knowledge of the weapons he is to employ. With a consideration of the important classes of remedial agents other than drugs this section is not occupied. Suffice it to say that the therapeutic instruction of to-day is incomplete without full attention to such agents as electricity, water, food, etc. In regard to that special class of remedial agents which we designate as drugs while the number in use is much less numerous, yet the knowledge regarding them is on a far more advanced plane than hitherto. The time has come when a course of lectures on materia medica and another somewhat similar but less descriptive course on therapeutics will not suffice for the needs of the medical student. Our medical schools must provide instruction in the department of pharmacology corresponding in value to that in other scientific branches, or their duty is unfulfilled. Courses in pharmacology must be equipped with facilities for demonstrating practically the effect drugs are capable of producing in the animal economy, and for investigating the properties of new drugs as discovered. It is not enough to tell a student that digitalis is the leaf of such and such a plant, that it contains certain active principles capable of producing such and such effects on the circulatory system. The student must at some time in his course see for himself the sphygmograph inscribing its altered record. Would a college tolerate a professor in geology or botany who confined his instructions solely to the amenities of the lecture room, however eloquent or inspiring his words might be? Shall we, as physicians, tolerate or content ourselves with less from the teachers in our departments of science? Already our medical schools are facing this question. Already are our leading schools inaugurating successful courses in experimental pharmacology. It is not a part of this discussion to say what shall or shall not be taught in this department. Let us limit ourselves still further to the simple question, How shall the medical student become familiar with the pharmacopœia? Here again the progressive hand of science commands us to initiate the student into the mysteries of the drugs he is to use just as the chemist or the botanist does in his chosen fields, and here it is

that we find that our profession, in its specialization, has not fully adjusted itself. Let me briefly indicate the old way which appears to persist in many localities, and then outline what I conceive to be a wise method of treating this subject. We all know of instances where the young medical student, too often ignorant of biological methods and knowledge, moreover, ignorant as yet of the pathology of disease, is introduced to a jargon of technicalities; in the early part of his course is informed that the pharmacopœia is the official organ of a learned committee representing the various medical and pharmaceutical societies and that it is revised to date every ten years; is treated to a learned course of descriptive lectures; is shown from the lecture table a host of bottles or a meaningless array of lantern slides or gaily colored plates. The wild Indian thought of killing a photographer because he found himself represented as a half man, he being unable to appreciate the effects of light and shade. It is hard to realize that the young student of science is no better off and must first be taught to read. His early steps in science are as those of the crawling infant. Is it to be wondered at that at the close of such a course, however eloquent the teacher, the average student votes *materia medica* a bore, throws away his pharmacopœia, if he ever had one, and, except for the purposes of an examination, knows absolutely nothing of that remarkable, erudite, and most useful work, the pharmacopœia, save in relation to a dozen or so drugs, which even then he is able to administer only in the crude, often offensive, ways of his hospital or dispensary experience? Is it any wonder that in his innate sense of the fitness of things, when he finds his private patients demanding agreeable-tasting and sightly preparations, he falls an easy prey to the first manufacturer who floods his office with attractive and plausible circulars, samples, and other baits of enterprising business greed? It is extraordinary that this matter has received so little attention at the hands of the profession. And it is a striking commentary on our carelessness, I may even say on our credulity, when our medical societies, even our great medical congresses, will content themselves with an exhibition of so-called pharmacy represented solely by the pretty preparations of a few manufacturing concerns, with here and there a patent food or water thrown in to vary the scene. The bait of a neat \$12 case with dainty tablets of all the drugs he remembers having heard his professor laud so highly is too much for him, and in his ignorance the medical tyro begins his career regardless of the fact that medicines change their properties with age, that pills will not always dissolve when wanted, that some may even pass the exit gate without effect, that the pretty tablets may irritate where soothing was indicated. He is fortunate if in giving two different kinds he does not some day blow up his patient by some unforeseen explosion; or if the unwitting patient, having been told to dissolve the compounds, has not saved most of the drug for a last, perhaps a fatal, dose.

There is no reason, gentlemen, why this subject should not be made as attractive and as valuable in a medical school as it is in the colleges of pharmacy. In them a new era has begun. We cannot all teach as Agassiz taught. Such a genius is one of a century, but any true teacher can make his student enjoy his study and come to it and take from it with the zeal and profit of the naturalist. This is done in our colleges of pharmacy, and can be done in our medical schools as well. The steps are the same in kind, the only difference being that the pharmacist in his line of specialization must travel further. Now, let us consider what these steps are. The young student of pharmacy is required to know enough of elementary botany and chemistry to understand the main anatomical and chemical features of the drugs studied. Should the physician be less well prepared? He is then given actual specimens, not merely lecture-table specimens, but actual hand specimens for his personal study—to taste, smell of, and look at, inside and out, to examine microscopically as well—then to keep for his private ownership, review,

and comparison with later specimens, to his heart's content. Having made his own observations, sometimes, to be sure, under the guidance of his teacher, he is then required to compare his data with the descriptions of an authoritative treatise. Such is our pharmacopœia. If he chooses to improve his phraseology by adopting that of those of greater experience than his own, he may do so, but that is of secondary importance. The fact is what is wanted, and the fact studied in such a way is the student's own. Instead of passing in one ear and out the other, it has come to stay, and has come in wisdom's way, which is a way of pleasantness. Our pharmacopœia describes all drugs now regarded as of value in language descriptive of results derived from study of such a character. Each student of pharmacy must practically make his own pharmacopœia in precisely the same way. Each medical student should make his own pharmacopœia, which of necessity must be still smaller, according to his special needs, in practically the same way also. Not having time enough for all he must learn types—for example, as *digitalis* leaves—then, though it would be well, he need not carry out every step in the study of other leaves as *belladonna* and *stramonium*. It is not his function to purchase fine specimens for the preparation of their active principles, nor to detect adulterants, etc., but before understanding the use of tinctures, fluid extracts, pills, etc., he must know something of the crude drugs from whence they came.

Next as to how he shall master what he should know regarding those preparations; and it is just at this point that our medical schools are most liable to fail, excepting a few who demonstrated, perhaps, a single percolate from their lecture tables. The older teachers contented themselves for the most part with stating that the pharmacopœia contained specific directions as to how these classes of preparations should be made. So it does, and soon the student of pharmacy learns to admire the care and painstaking with which the best methods for making the many preparations of the pharmacopœia are presented. It is important for the pharmacist to be familiar with all. It is not so for the medical student. Nevertheless, he must know the types, or he will soon be making the needless errors which make him present so pitiable a spectacle of ignorance to the pharmacist, and become so dangerous or obnoxious to his patients. The neglect of instruction in such matters in our medical schools is a discredit to our profession. If it is worth while using tinctures, etc., in our practice, it is worth while knowing something about them; and, as with every other objective study, there is no better way of learning about a thing than to see it and study it objectively. I would have every medical student understand the classes of preparatives of our pharmacopœia. I would have him make in the laboratory at least one illustration of each. I would have him blend them in various ways just as he is to order them blended in his later practice. Thus he would soon learn the beautiful and nice proportional relations presented in our pharmacopœia as existing in the strength of these various preparations. He would soon learn to avoid incompatible and unsightly mixtures. He would soon know what he wants to use and how to direct its preparation. Fancy a captain ignorant of the manual of arms. That is about the position of many a student of the old régime regarding the mixing and prescribing of drugs. But a new era is at hand, and it is noteworthy that those colleges which equip their students in such a practical, scientific way furnish our profession with men who find their studies full of interest and have become the foremost physicians and therapeutists of the country.

---

#### DISCUSSION.

Dr. H. H. RUSBY. The idea has been advanced that the possession of this knowledge of pharmacy would tend to induce the physician to dispense his own medicine. My own idea has always been that, on the contrary, it would give him an adequate idea of the importance of the subject, so that they would not "rush in

where angels fear to tread." I always tell my students and inquiring friends that the University of Pennsylvania has the best medical course in the country. The institution which has the wisdom to introduce this study has good wisdom for use in other directions.

Dr. A. W. MILLER. The paper to which we have just listened reminds me very forcibly of the remarks which I am in the habit of annually making to the students of the University of Pennsylvania. As near as I can recall, I have there for years advocated the same reforms which he has recommended. It is a part of the educational plan of the medical department of the University of Pennsylvania to make the study of pharmacy obligatory on all of its students, excepting those who are either graduates of pharmacy or have had several years' practical training in drug stores. During the first course of medical instruction the student is compelled to devote one whole evening, that is, from 7:30 to about 10 o'clock in each week, to practical work in the pharmaceutical laboratory, including practice in the writing of Latin prescriptions. I have again and again been assured by many of our graduates that they have found the practical instruction in the pharmaceutical laboratory to be of greater benefit to them than that of many other laboratories.

### ADDRESS OF THE PRESIDENT OF THE SECTION, HON. ALONZO GARCELON, M. D., LEWISTON, ME.

Although four centuries have elapsed since the discovery of this continent and its occupancy by the civilized nationalities of the world, now for the first time since that important event the medical profession of the various governments into which it is subdivided have, by their delegates duly appointed, assembled this the 5th day of September, 1893, for the purpose of conferring together and discussing subjects of especial importance not only to themselves but to the communities they represent. With the end in view that the best results attainable may be

secured, the committee on organization have arranged for the meeting of sections for a discussion of special subjects, among which is that of medical jurisprudence, a section of great importance but seemingly a sort of *bête noire* to both the profession of law and medicine. The literature of the subject is meager, and buried for the most part in the intricate labyrinth of medical and law reports, jury trials, and legal decisions. Our institutions for instruction pay but little attention to the subject and make but little or no provision for giving their students even a hint of its importance and bearing upon the happenings and well being of society. If, as our most distinguished lexicographer asserts, jurisprudence is the knowledge of the law, customs, and rights of man in a state or community necessary for the due administration of justice, and that its study next to that of theology is the most important and useful to mankind, what are we to say of those schools, whether of law or medicine, claiming to stand in the front rank of all important teaching in whose curriculum such a term as medical jurisprudence has no place and whose graduates go forth with as little knowledge of the importance of the subject or of their daily liability to be engaged in cases where the property, the freedom, the reputation, or the life even of some one or more persons is involved as the newborn babe has of the alphabet. In the broad catalogue of murders from whatever cause, there is scarcely a case in a thousand brought into the courts but demands the testimony or opinion of a medical witness. A brief allusion to some of the occurrences which every member of the medical profession in his daily walk through life is liable to meet with should convince him of the importance of the subject and impress upon him the necessity for appropriate preparation. Insanity, that mysterious, manifold, and ever to be dreaded disease, is ever present with us. Its form is protean, and in numerous cases it is difficult to determine its existence. Horrible crimes are committed under its influence, but others of equal atrocity are actuated by malignity, revenge, avarice, or some other cause, and the plea of insanity in some of its protean forms is alleged as justification or excuse. We have not only monomania, dypsomania, kleptomania, moral mania, but emotional mania and a host of other manias so numerous and varied that it seems possible to classify the whole human race under some form of mania, or in other words to declare that we are all maniacs. In these days, when the invention of new terms seems to be regarded as a recommendation of merit and every author upon almost every topic seeks a new classification, the medical man who is called upon to testify oftentimes finds himself in a most embarrassing position if he is not well posted upon the subject at issue in all its ramifications. Writers upon insanity form no exception. The classification of Esquirol, who is recognized as standard authority, is modified by Ray and rendered more complex. Flemming is still more so. His first divisions are two: Imbecility and mental confusion. Imbecility he subdivided into origin and extent; mental confusion into disorders of temperament, disorders of the understanding, and general depravity, and his subdivisions are run out into extremely fine points. Wharton and Stille adopt this classification, saying "it is very valuable both for the delicate precision of its analyses and for the important aid it affords to the nomenclature of forensic psychology." In looking over these classifications by such authorities and such divisions and subdivisions we find such terms as "anosia," "oikeiomania," "pyromania," "oideiomania," "pseudomania," "faraticomania," and hosts of others. The ordinary practitioner might think that the writers had themselves run mad. It must be remembered, however, that as these divisions and subdivisions are found in all the books on insanity the attorney has a right to demand, when a medical witness is placed upon the stand, if he has given the subject especial attention, that he will be able to assign to each case its proper class; and if he fails to do so, as he very likely will if in the hands of a sharp examiner, he is regarded as an ignoramus or pretender, and leaves the

witness stand mortified and ashamed and a laughing stock to the gaping crowd in attendance. The attorney is disgusted, the judge astonished, and the jury in greater doubt than at the beginning of the investigation. It is therefore of the greatest importance that every man who enters the field of practical medicine should be a man of thorough education in all departments or forms of mental alienation. It is not to insanity alone, however, that the attention of the physician is most frequently directed or his opinion demanded in cases involving medico-legal investigation. Death under suspicious circumstances is of lamentably frequent occurrence. Was it the result of accident, suicide, or crime? Did the sandbag, the stiletto, strangulation, or the bullet do the deed? Was anæsthesia or poison the cause; and if so, which and what? Was there latent disease of the heart or other organ to account for death? To the medical examiner a wide field for investigation is opened. Science has done wonders in aiding the detection of crime, but at the same time it may be by no means certain that it has not done much more in aid of its commission. Hence the importance of thorough work. The negative as well as the positive must be proved. If such as are more frequently employed are not found, others must be sought for, and the search continued, having in view the purpose to let no guilty party escape.

Apart from the liability to be connected with medico-legal examinations previously alluded to, and to which every physician is subject, there are others of great importance demanding a thorough education of the practical practitioner. In cases of divorce, protracted gestation, premature labor, and impotency important interests are often at stake and the knowledge of the medical witness put to a severe test. The very earliest work found in looking over the bibliography of medical jurisprudence is one published in 1612 by Tagereaux, entitled, "*Discours sur l'Impuissance de l'Homme et de Femme.*"

In 1714 an important case was tried in Paris involving the question of impotence which gave rise to the publication of two volumes entitled "*Impotentia; the Case of Impotence Debated in the Late Trial at Paris.*" Closely allied to this question are those of protracted births, *naissances prétendues tardives*. About 1765 a contested case for divorce or inheritance gave rise to several treatises by such authors as Bouvart, Barbeaux, Bas, Bertin, and a year or two later a work in two volumes by A. Petit. I doubt if any better résumé upon the subject can be secured in works of more recent date if such are in existence. In a community when great wealth and loose morals are frequently allied, when criminal abortions are numerous, and injudicious marriages frequent, divorces easily obtained, maternity revolting, and attention to the care of a family incompatible with social life, the dance hall, the theater, the card table, and other amusements, it would not be surprising if medical men were more frequently summoned to give evidence in medico-legal trials involving some one of the various crimes to which allusion has been made.

Enough, however, has been said upon this branch of the subject to give a hint at least of its importance, and we will pass to the consideration of cases of a different type, but of vast importance to municipalities, corporations, and individuals, which very frequently require the testimony of medical men to secure settlement. I allude to those arising from defects in the public highways, railroad accidents, explosions, want of proper supports or defective hoisting apparatus in mines or manufactories. In cases of injuries of this nature, whenever the municipal officers, railroad officials, or agents of corporations refuse to settle upon terms which the injured party believes to be just, and where there was an absolute defect or gross carelessness on the part of the corporation, he appeals to the courts, and a medico-legal investigation becomes a matter of necessity to determine the extent and nature of the injury. In many instances medical experts, in addition to the injured party's attending physician, are called upon to give testimony in the case.

It is now a common practice with our railroad corporations to enter into a contract with one or more surgeons to attend upon cases of injury occurring on their respective lines, and such is human nature that almost constantly the weight of their testimony is found to favor the interests of their employers and minimize the degree of the injury sustained by the sufferer. On the other hand, the injured party is quite as apt to magnify his suffering, and with the hope of obtaining excessive damages sometimes claims to suffer from causes not apparent and which are without foundation. Particularly has this tendency been observed among those who have brought actions against municipalities. Municipal officers, like railroad surgeons, have an interest at stake, and oftentimes very unwisely refuse to do that, as expectants for future election, which they would do as disinterested parties. They refuse to make a reasonable compensation, if any. The injured party is determined to have a pecuniary remuneration not only for injury, but for suffering endured, lapse of time, and for anticipated infirmity. The attorney is consulted, perhaps a shyster ever seeking to encourage suits, who advises that no settlement should be made, but that action be brought at once. This done, the plaintiff's difficulties make no improvement. Indeed, they seem to increase. He can not step with the same firmness. His spine is now painful. His lower extremities have lost their feeling, and he feels he is permanently injured and a confirmed cripple for life. The case comes to trial. Experts are consulted. Every physician who has had aught to do with or examined it is summoned. He goes upon the witness stand, and with lugubrious countenance details his condition and sufferings. The jury is touched by his narration. The weight of evidence favors his plea, and a handsome verdict is the result. He leaves the court room with the sympathy, it may be, of the mass of spectators. In a few weeks a remarkable change has taken place. His general appearance has improved. He moves with greater certainty. His cane, or crutches, as the case may be, is laid aside. Some good lady has recommended a favorable panacea, it may be goose oil, or stork's oil, or some wonderful plaster, from which he has received great benefit. It is truly surprising what an effect it has upon him, and he now has great hopes of a permanent cure. This is no burlesque description of actions of this type, and I doubt not its parallel has fallen under the observation of every man who has been an observer of cases of the kind described. Quite a number have occurred under my own observation during a half century's practice. I trust you will pardon me if I give a single instance, one of actual occurrence, in all its details and from which a deduction valuable to every medical witness may be drawn:

A minister of the gospel in regular standing in the society to which he belonged was thrown from his carriage while crossing a railroad track and received an injury of the spine, as he alleged, which confined him to his bed and house for quite a number of months. It was in dead winter and a deep snow lay upon the ground. The snowplow had thrown quite a ridge of snow upon the side of the track, and as the roads crossed each other at quite an oblique angle sleighs were quite easily overturned. There was no question as to the defect in the highway, but a dispute between the town and railroad as to the liability. Both declined to settle the damages claimed. After a delay of a year, more or less, a suit was brought against the town. In the meantime the injury did not improve, but grew apparently worse. Numerous physicians were consulted, but the trouble did not abate. His crutches were his constant companions, and all medicines failed to relieve his suffering or restore the action of his limbs. He was sure he was a cripple for life. He spent much time in hunting up evidence and creating sympathy for his misfortune. At length the case came to trial. When he entered the court room he could walk only by aid of his crutches, and when upon the stand the story of pains by day and torment by night was painted in the glowing colors of an eloquent divine. A minister of the gospel could of course tell nothing but the truth, and as pain and suffering can be felt only by the sufferer, and the extent of the injury of the spinal column not always possible to demonstrate, and the prognosis not by any means certain, an award was rendered the plaintiff in this case of nearly \$3,000. The award was made at the April term of court and the

plaintiff hobbled from the court room with apparent difficulty. Not more than three to four months afterwards I was aboard a railroad train on my way to a neighboring city, and as the train stopped at a way station for the reception of passengers a gentleman entered the car which I occupied who strongly resembled the plaintiff I had last seen in court. But as he walked without crutch or cane, I at first thought he must simply be "a double," to use a favorite phrase of the late Prof. Dixy Crosby. Closer scrutiny convinced me that I was mistaken, and that he really was the man in question. Of course my curiosity was aroused to learn by what means so great a transformation had been so suddenly and so effectually secured. I seized an opportunity to speak with him. In answer to my inquiry he replied: "Thank the Lord, it is the result of prayer. I retired at night after having prayed long and fervently that I might be restored to health, and when I awoke a feeling came over me that I should recover, and when I got out of bed I found that I could stand without the aid of a staff. I then made the attempt to take a step, which I did. I then tried another and another, until I had walked to the bureau across the room; and since that time, praise be to the Lord, my health and strength have wonderfully improved." I am sorry to add that there are many familiar with the case who are so very wicked that they put but very little confidence in the cause of the cure.

In the course of a professional experience of more than half a century I have had the opportunity of observing the history of nearly a score of medico-legal trials of this character, and, while no others have attributed their recovery to the efficacy of prayer, the larger proportion have recovered very rapidly after an award of damages in their favor. My advice to professional men who are summoned to give testimony in a medico-legal case where a question of damages is involved is not to be too positive as to their prognosis.

In the early years of my practice I had a patient who received a severe injury of the spine in consequence of an obstruction of the highway. She was a severe sufferer for many weeks, and damages were claimed. I advised both parties that a mutual agreement would be the best for all concerned, especially as there was no question of the unlawful nature of the obstruction or want of care on the part of the plaintiff. At the request of my patient I named a sum which I thought to be small enough in all reason. The municipal authorities were unyielding, thinking that my judgment was biased in the lady's favor, and chose to test the case in the courts. There was living at that time in a distant city a distinguished gentleman and surgeon of eminence who was frequently called as an expert and whose opinion with judge and juries was equivalent to law. His grand personal physique and dogmatic method of expression gave him a commanding influence. He was called by the authorities to give his opinion in the case. He visited the patient, learned the history and progress, and when he was asked by the town's attorney as to the prognosis or probability of recovery he very positively declared it to be unfavorable, with no hope of improvement. He had been familiar with injuries of like nature and he would not admit of a reasonable hope. Such was the effect of his testimony that the jury awarded damages about four times what the plaintiff would have obtained by my advice. The result was that within six months she was able to go about her house, and in less than a year and a half after that was able to attend to the ordinary domestic duties of her family, and for many years has enjoyed excellent health. The "*vis medicatrix naturæ*" oftentimes produces unexpected results, and it is not wise to ignore its possibilities or honest to attribute to inert prescriptions and panaceas her potent influence.

Let us now pass to the consideration of another class of cases, by far the most frequent which occupy the courts and most especially affect the reputation and pockets of the practitioner. There is not a member of the profession who is not liable, justly or unjustly, from malice or jealousy, for the purposes of blackmail, or for some cause beyond his control, to be summoned into court to answer to a charge of malpractice. The frequency of suits for damages, as well as for criminal practices, are alarming both to the profession and to the public. As to the latter, I am quite sure, frequent as they are, not a tithe are ever exposed to public gaze and the culprits brought to the bar of justice. There are without question many men in the ranks of the profession bearing diplomas which qualify or rather entitle them to rank as members in regular standing, who do not hesitate for filthy lucre to run the risk of exposure and disgrace, and subject them-

selves to the penalty attached to their crimes, hoping, as all criminals do, to escape conviction. As to civil actions, they will necessarily occur so long as ignorance and incapability are prevalent in our ranks. But neither ignorance nor incapacity are the sole grounds of actions of this nature. Men of ability, experience, and education are sometimes brought into court and subjected to heavy expenses without fault on their part, owing to the prevalence of the opinion that certain results are the proof of want of skill. These actions arise mainly as the result of amputations, dislocations, and fractures, but sometimes of incised wounds and operations upon the eyes and other organs. So frequent have been these actions that some practitioners absolutely refuse to attend upon surgical cases at all. It is but a few years since the committee upon the subject reported to the Ohio State Medical Society "that in their opinion the subject of malpractice was of more importance to the profession than any other connected with surgery." They say, "There is a standing and accumulative evil—an evil bearing with the weight of an incubus upon the profession." The cases reported, with several not included in the report, were forced upon the attention of a single member in the past year. During one week, in as many different counties, four cases were tried.

These statements are all illustrated by several cases, in each of which the alternative was presented to the surgeons, all of whom were regarded as well educated men, either of compromising not only their own reputations but the honor of the profession by paying damages, or a trial in court, when a verdict in their favor would be attended by loss of business and heavy expense in carrying on the trial. It is unquestionable that many cases of this kind occur, but how many will never be known, as there is no possibility of obtaining a record. But, on the other hand, there are numerous instances, judging from my own observation, where it would be simple justice that the incapacity and ignorance of the pretended surgeon should be exposed by a public trial. Judging from my own observation and the deformities so frequently noticed, after making all due allowance for unreasonable prosecution, I am convinced that there is a vast amount of ignorance and incapacity in the treatment of wounds and injuries of the human system, and I feel equally certain that the average acquirements and natural ability of the great majority of professional men in the region of my observation will compare favorably with an equal number in any section of the country. The truth is the medical profession, like that of law and theology, embraces quite too large a proportion of imbeciles who are unfitted both by nature and education for the practice of any profession. A few cases in illustration will need no apology :

A little girl of 5 summers received a fracture of the right femur at or a little above the junction of the middle with the upper third. An uncle of the child was the physician of the locality, and took charge of the case. After a period of ten days, the sufferings of the child had so worked upon the feelings of her parents and grandparents that the latter insisted that counsel should be called, to which the doctor was decidedly opposed. He was overruled, and my services were decided upon. The doctor himself came for me, saying that nothing was to be done at this stage of the case, and that ossification had probably taken place. Upon this representation I declined to go with him, but yielded to his solicitations and to the assurances that whatever was necessary might be done. It was midsummer. The best feather bed in the house had been appropriated for the comfort of the little sufferer, and it lay ensconced in its folds. The sheet being removed I noticed, even before the dressings were removed, that the upper and lower portions of the shaft of the femur formed an angle of not less than 45 degrees. In reaching down to examine a little more critically the kind-hearted, anxious mother, seizing my arm, exclaimed, "Surely, doctor, you will not do anything to the limb! The doctor says she will die if it is disturbed." An examination disclosed the fact that the only support or dressing applied to the limb consisted of four little splints, 1 inch in width and less than 4 inches in length, applied to the limb with a roller bandage, and as the fracture was considerably above the middle of the shaft there was absolutely nothing to prevent the free movement of

the broken shaft whenever there was a movement of the body. The upper extremity of the shaft was drawn forward and the limb shortened nearly or quite 2 inches.

A gentleman from a distant State, on a business tour, was thrown from his carriage, receiving a compound comminuted fracture of one of his legs near the middle, while passing through a neighboring village, some 20 miles distant from my residence. The accident occurred directly against the residence of the village physician, who kindly proffered the use of his house and his attentions in the treatment of his case. Two weeks later I was called for consultation. The surroundings were comfortable; the bed a mattress on which was a bed of feathers, and across this a folded comforter, so called in New England, the lower folded edge of which was so placed as to come about on a line with the fracture of the limb, permitting the heel and lower extremity of the fractured limb to drop several degrees and causing quite an angle at point of fracture. Two strips of board were used,  $2\frac{1}{2}$  inches in width and long enough to extend from upper extremity of the tibia to the bottom of the foot. Short pieces of red tape were attached to the top edge of these strips and the apparatus was placed by the side of the limb and not confined to it in any manner save by tying the strings of tape together over the top of the leg. A long piece of similar tape was tied in the middle around the great toe of the fractured limb and the end of the strings were attached to opposite footposts of the bedstead. A poultice was applied over the wound, which being removed, a denuded portion of the upper extremity was brought to view, and beneath, a large collection of pus. Two attendants were present, who stated that they had been in constant attendance from the first hour of the injury, either one or the other constantly holding the limb to control its spasmodic action, which was extremely frequent and intensely painful. The suffering of that fortnight can be imagined quite as well as described.

A lad of 12 or 13 years of age playing with other boys fell from a sidewalk to the street and both bones of one arm were broken. The doctor of the village, with some claims as a surgeon, was called to attend the case. He claimed to have reduced the fracture, but as there was a tendency to a little more bulging or prominence over the region of fracture, he thought to remedy the defect by tightly applying the bandages over the splints. Notwithstanding the young patient suffered extreme pain, he declined to make any examination or remove the dressing before the eighth day, when to his astonishment the entire hand and arm was in a state of gangrene as high up as the fracture, except a little strip along the under edge of the ulner to the wrist joint, three-fourths of an inch in width. The result was an amputated arm. The bones were found overlapping each other, and without question reduction had never been made. It would seem that nothing short of ignorance could be pleaded as an excuse for such a mistake and a want of that faculty commonly called "common sense."

I have not cited these as unique or without a parallel, but on the contrary their type is found in every community, and I have the impression that there are but very few professional men of long experience who have not met their counterpart in one form or another. And let it not be said that these men were "wicked beyond all who dwell in Capernaum," for they were all graduates of some reputable medical college and stood on a par with a large majority of those who annually go out upon the community with diplomas in their pockets. Nor let it be suggested that they were graduates of a bygone generation who had not the facilities of a medical education in a reputable college. If the report of the qualification of a graduate given in the Journal of the American Medical Association be true, as it unquestionably is, no limit can be given to the stolidity that may be rewarded with the prize of a diploma, even at the present day. The truth is these men, like thousands of others, had mistaken their calling. They had no mechanical ingenuity, and you might as well attempt to make a musician out of a child with a cleft palate as a surgeon out of a man deficient of mechanical ingenuity. Natural abilities, supplemented by the best education with assiduous application and perseverance through a long course of study secure, are absolutely essential to qualify any young man for the duties and the responsibilities of the practice of medicine, and with all these can give him he will soon find that he has but just entered upon the threshold of the temple of knowledge, and when he enters upon the domain of surgery he will find that something more is wanting than a knowledge gathered from books.

In the remarks I have thus far made I have endeavored to illustrate the importance of the subject of medical jurisprudence and its demands upon the members of the medical profession, their responsibilities and liabilities, both as witnesses and defendants. It is true that as defendants it is almost always in the capacity of a surgeon that the medical man is called to account, but it is not less true that there is quite as much more ignorance and malpractice in the treatment of ordinary diseases as in the management of surgical cases. But dead men tell no tales, and as a general rule the effects of the incompetency are out of sight and accounted for on other grounds. It is not to be expected that incompetency and ignorance will be weeded out of the ranks of the profession, but by united effort a great advance can be made and the evil reduced to a minimum. To accomplish this result the work must begin at the foundation. The body politic must be educated to a just appreciation of the importance of furnishing proper means and opportunities for acquiring a thorough training, throwing such restrictions around the facilities as will keep at bay all dotards and incompetents. Take away the right of practicing medicine by virtue of a diploma from medical schools without an examination by a competent board of medical examiners. To this end the physicians must coöperate. In fact the work must be done mainly by themselves. There is already in the field an army of faithful workers. The American Medical Association was started fifty years ago for this very purpose. It has done much, and yet how little. There are mountains of prejudice to be undermined. The great body of the profession is lukewarm toward improvement, and refuses to coöperate with those who are laboring for the best interests and glory of the world and the well-being and happiness of the people. Of the 100,000, more or less, practitioners of medicine in this country, less than 5,000 are enrolled as members of the association. There ought to be at least 80,000, marching in solid column to the halls of Congress, demanding the establishment of a national university such as the world elsewhere does not furnish the equal, opening its doors freely to all who could pass the ordeal at the gates of its portals and remaining only so long as an annual examination certifies to their ability and efficiency. Our State organizations and local societies must press on the work and demand of our State governments to require proper qualifications for admission to the ranks of the practitioners of the healing art. Medical colleges organized by State authority should require a certificate of qualification by the State board of medical examiners before admission to their halls. The standard of qualification should be fixed by a national board. Local schools of instruction and individual practitioners in State and county should require a certificate of qualification of literary or scientific attainments according to a standard adopted by their respective State societies. The adoption of such a system would in a few years fill the ranks of the profession with capable and efficient recruits and relieve it of the incubus under which it rests. And I am very sure in a comparatively short time questions of medical jurisprudence growing out of malpractice would be relegated to past ages, and ignorance and stupidity find no standing place in the ranks of a profession that has no equal in its importance and utility to the suffering of the human race. Of the status of the subject in our sister Republics I have no knowledge, but trust our confrères will enlighten us, and trust that the discussion that follows will prove of mutual benefit and give us all a higher appreciation of the importance and responsibilities of the subject of medical jurisprudence.

## PAPERS READ BEFORE THE SECTION.

## CHANGES IN THE MANNER OF CONDUCTING CASES OF CRIMINAL POISONING.

By R. OGDEN DOREMUS, A. M., M. D., LL. D.,

*Professor of Chemistry, Toxicology, and Medical Jurisprudence in the Bellevue Hospital Medical College, of New York.*

Having been engaged in studying, teaching, and practicing the subject of toxicology for over forty years, I may be pardoned if I venture to suggest to your honorable body certain important changes in the manner of conducting cases of criminal poisoning. Great discredit to science has resulted from the discrepant testimony in courts of justice between experts in pathology and in toxicology. Both judge and jurors are bewildered. To decide between the learned contestants is difficult. All who have attended criminal trials involving such scientific testimony, either as witnesses for the prosecution or for the defense or as interested auditors, are familiar with the efforts often made to impugn the experts. Questions are asked derogatory and detractive, sometimes almost insulting in their character, intended to disconcert and annoy the witness. Instead of the calmness and self-possession which should be the privilege of the expert, he is not only irritated and annoyed, but must exercise his wits in attempting to meet the attacks of members of the bar, who from constant practice in courts acquire a skill he rarely possesses. There are most competent and superior pathologists and chemists who are debarred from participating in these cases, and the court deprived of their valuable knowledge and experience, from a dread of being exposed to ridicule and contempt by pettifogging lawyers. I respectfully propose that in a case of suspected poisoning the coroner, the district attorney, or the court allow the arrested party to have his or her representative pathologist present at the autopsy with the pathologist selected by the prosecution. Also a toxicologist, who, with the chemical representative of the State, shall decide on the parts of the body to be removed for analysis, and that the two experts shall conduct the research together. If the prisoner is unable to bear the expense necessarily involved, I would insist that the court should provide for the same, as has long been the custom in appointing legal aid for those whose means deter them from engaging counsel. Of course the investigations should be conducted in pathological and in chemical laboratories, to which no one should have access excepting the experts. Such laboratories should be locked and sealed by each investigator when leaving, and one should not reënter the laboratories unless the associate is present, each breaking his own seal. As mere traces of poison can be detected, it is essential that the chemical laboratory should be provided with new glass and porcelain vessels and as pure chemicals as can be procured. In most cases the first duty devolving on the experts would be to purify said chemicals. After consultation the chemists would agree on certain methods of procedure known to them and which appear in detail in works on toxicology. They would keep separate records of each step taken in the research. They would simultaneously witness the changing or evanescent color reactions, as in alkaloidal poisons, and where doubtful repeat them until their conclusions agree. Where possible, they should reserve as exhibits in court at least portions of the poison or poisons discovered in the various organs of the body or from the contents of certain of them. Neither time nor care should be spared in making the researches complete and harmonizing in their deductions. The advantages accruing from

this mode of procedure would be the avoidance of discrepant testimony; moreover, the findings of the pathological and chemical experts would be accepted as facts. This would not only prevent opprobrium being cast on scientific researches and restore them to their eminent position with the community; but as the prolonged and tedious wrangling of the opposing litigants in regard to expert testimony would be avoided, it would diminish the labors of the court, the counsellors, and the jury, thus facilitating a just decision.

It is painful to consider the manifold duties of the jurors. Taken from their occupations and from their homes, confined many hours each day in the vitiated atmosphere of a crowded court room, they must attentively listen to the details of the circumstantial evidence, to the testimony of various and varying experts in medical practice, pathology, and chemistry; hear the discussion of scientific matters, in terms unfamiliar to their ears, by the prosecuting attorney and the legal defender of the accused, and after instructions from the judge on legal points attempt intellectual digestion of the incongruous mass and harmoniously unite on a verdict. What wonder if one or more of them should succumb under this combination of conflicting considerations. More effectively to impress this subject, let each one who has patiently followed these considerations suppose that he was under suspicion or arrest for the cowardly crime of poisoning. No matter how distinguished the pathologists and the chemists appointed by the court or by the prosecuting official, would he not earnestly desire that his own representatives should be present during the investigations involving his reputation and possibly his life? I, for one, most certainly would. I have zealously taught this doctrine in my lectures on medical jurisprudence to the students in Bellevue Hospital Medical College.

I would respectfully commend another theme for the consideration of your honorable body. I have keenly felt great antipathy in being obliged to testify in a court room open to the public, and always partly filled with those of the gentler sex, to extraordinary methods of poisoning, even through the genital organs, and to other matters unfit for ears polite, yet essential in the trial. Testimony has frequently to be given and discussed of immoral practices of the accused which afford instruction in evil ways it were better should not be presented to the community. St. Paul wrote to the Corinthians, "Evil communications corrupt good manners." Though nineteen centuries have elapsed since this wise record was made, human nature has not risen above its applicability. Hence, I would strenuously urge that when such testimony as referred to has to be offered that the presiding judge should allow only the necessary officials and the jury to be present. Furthermore, that the representatives of the press be excluded at the same time. There are some journals of extended circulation that boast of publishing accurate details of every *cause célèbre*.

While the judicial halls can contain but a few hundred persons, who may listen to disgusting and demoralizing narrations, the newspapers distribute the same to millions of readers on the American and European continents; in fact, around the world! The strictest scrutiny is conducted forbidding the sale of immoral photographs; yet pen pictures of a most indelicate and heinous character are purchasable for a trivial sum of money, and read, not only by adults of both sexes, but by boys and girls, and discussed in the streets, in public vehicles, and even in the sacred precincts of home, where purity of thought should never be tarnished. This proposition may be considered Utopian, and contrary to the principles of a republican and free government; yet thirty years ago, when imperial rule existed in France, this method prevailed of excluding the public and the press, at certain portions of the trial, when testimony of the character described was to be given. During the years 1862 and 1863, while residing in Paris, I was invited by members of the French bar to attend certain important criminal trials, and can

bear personal testimony to witnessing the clearing of the court room of its auditors and of reporters, the legal representatives alone being allowed to remain when themes of an immoral nature, yet essential for the administration of justice, were to be presented.

A third important element in the proper performance of a toxicological research is a fitting remuneration to the expert for his elaborate work, which may involve weeks or months of his skill. He must also have frequent consultations with the coroner and the district attorney. The latter officer he must instruct in the details of the chemical analysis, to arm and equip him for attacks from the defense and to protect his own witness. I am proud to say that many eminent members of the bar, renowned in criminal trials, have honored me by working faithfully in my laboratory to familiarize themselves with the chemical reactions. The expert for the State must not only prepare his exhibits for the court, deliver his testimony, and submit to rigorous and sometimes to insulting cross-examination, but he must also be present to hear and suggest criticisms of the experts for the accused, involving additional time. The presiding judge and the prosecuting attorneys, as well as the coroners, are salaried officers. Distinguished counselors for the defense receive generous fees. Up to the year 1858 the well-known toxicologist in New York City, Dr. James R. Chilton, informed me that he received, two or three years subsequent to his analytical labors in a poison case, the sum of \$25. The same custom prevailed in Boston even many years after the period mentioned, as told me by the eminent chemists, Dr. Charles T. Jackson and Dr. Augustus A. Hayes, of that city. This small fee did not warrant the expense of special laboratories and new vessels. The analyses were conducted in their ordinary laboratories, where visitors were daily received. This was manifestly unjust to the accused. A large majority of the better instructed citizens of the United States are ashamed of the inadequate compensation given to our public officers. It applies to the President, to the members of his Cabinet, to officers in our Army and in our Navy, to our foreign representatives, and to the judges of the Supreme Court of our country. It also appears in our institutions of learning. Prof. E. N. Horsford, when occupying the Rumford professorship in Harvard University, told me that young men of superior intellectual gifts and graduates of that college had to differentiate between a business career with marriage, and a possible professorship with celibacy. In the summer of 1885 the distinguished chemist, and one of the authors of the valuable work entitled *Forensic Medicine*, Prof. C. Weymott Tidy, while we were discussing the subject of medical jurisprudence at his residence in London, stated to me that he had abandoned making toxicological analyses for the Government. I replied "I think I know the reason for this decision, so unfortunate for science. To use an American phrase, 'It don't pay.'" He honestly acknowledged that I was correct. I told him I was proud of having broken an equally unjust custom in New York. That in 1858 (now thirty-five years ago) I declined to undertake an important poison case unless promised proper remuneration. I explained to the authorities that I should require an especial laboratory and a dissecting room, to be kept private, with doors locked and sealed during absence therefrom; also new glass, porcelain, and other vessels; likewise pure chemicals. That matters might arise involving more time than anticipated at the outset; that either the district attorney or one of his associates would have to be instructed in the actual manipulations involved in the research. My predictions were verified as to the additional work; for, besides analyzing the entire body of the deceased, that had been buried for twelve months, and discovering arsenic in every part of it, an entire second body was analyzed to determine the question of normal arsenic, which at that time excited public attention. I was happy to state to Prof. Tidy that the presentation of the importance of just returns for such professional services was successful, not alone for this particular case,

but for subsequent ones. Thus the ancient, unjust custom was abolished in New York City. Ere long it spread through the country. I have many times been solicited by toxicological experts to express my opinion as to the justness of their charges for services rendered where their bills had been contested. I respectfully but zealously urge that the medico-legal and toxicological sections of the Pan-American Medical Congress discuss and ultimately advocate the three features in criminal poisoning cases I have taken the liberty to suggest.

---

#### THE MEDICO-LEGAL ASPECTS OF FRACTURES FROM A CONSIDERATION OF THEIR ETIOLOGY, DIAGNOSIS, PROGNOSIS, AND TREATMENT.

By THOMAS H. MANLEY, A. M., M. D., New York.

The disorganization of bone from traumatic influence, fractures, belongs to that category which may be designated as serious surgical lesions. Of all lesions of this class, fractures are by all odds the most common. Every practitioner of the healing art sees them, and all, or nearly all, are assumed to be competent to properly treat the simple types. No age, sex, or condition escapes them. In varying degrees, according to the age of the patient, general health, and character of the lesion, they always leave a defective limb. In early life nature affects her work of repair so perfectly in many, when appropriate treatment is instituted, that the patient, after adult years are attained, is scarcely conscious of any impediment in function or diminution in strength in the former injured limb. It is only when the limb is put on a severe, protracted strain, in the event of sudden changes in the weather, or as one advances into old age, that he is reminded by a sense of weakness, twinges of pain, and a tender point over the seat of injury that the integrity of the limb was ever damaged. Many types of fracture in early life, by the simplest method of treatment, undergo prompt repair, leaving no visible evidence of their presence. Others, regardless of what measures may be instituted or of what skill and experience may be brought to bear in their management, never unite by an osseous isthmus, thus shortening or deforming the limb. Although time and custom have sanctioned the division of fractures into two groups, the simple and compound, this is but an arbitrary arrangement and tends rather to confuse than to elucidate, for all fractures are essentially compound or complicated. Not a few so-called simple fractures are more difficult to manage and leave greater deformities than those designated as compound. It is not infrequently quite impossible to definitely diagnose a fracture. Many fractures extend into the neighboring articulations, or are complicated with more or less luxation. As the union of a fractured bone is effected by two distinct processes; by primary intention, without a callus; or by extensive homologous cell proliferation, with a provisional mass encircling the ends of the bones (in a considerable number as early as the second week); it may be quite impossible to say from any physical examination, without the employment of considerable force, whether or not the bone had been dissundered. In a general way, it can not be said that the antiseptic treatment of wounds has in any manner revolutionized or improved on the principles recognized for ages as appropriate in the management of simple fractures, though since Listerism and cleanliness have been introduced, osteotomy has been more freely practiced for distortions of bone and non-union, with better effects, than before they became current with the profession.

## MEDICO-LEGAL QUESTIONS IN THEIR RELATION TO THE ETIOLOGY, DIAGNOSIS, AND TREATMENT OF FRACTURE.

It might seem on first thought that a question of litigation or jurisprudence could scarcely enter into the consideration of the causation of a fracture, but there are many cases on record in which actions in civil and criminal suits have rested mainly on this feature alone. The situation and extent of injury have not been disputed by the defense, but they denied their responsibility by alleging that the plaintiff was injured in another manner than that represented by him or her. Cases of this description are not uncommon. The inducement, by a little connivance with the unscrupulous, to turn an accident to good account very often is very great. As individuals and corporations are almost wholly at the mercy of the surgeon, in these cases it behooves him under all circumstances, when he has the least suspicion, to examine the patient critically for surface lesions and demand from him a full and complete account of how the injury occurred. In many the physical examination alone will not decide the quality and extent of force sustained; whether it was direct or indirect; or whether his body came in contact with an object or whether he was struck by an object. When we remember that fracture in rare instances may ensue from muscular violence alone, we can the better appreciate the difficulties which beset us in many of these cases in which fraud is suspected.

It is always of prime importance in every case of fracture to investigate the patient's general condition, or at least we can casually make note of it. Is he deaf or nearsighted? Is he a rheumatic, gouty, or syphilitic subject, or is he in greatly reduced general health? Has he ever been injured before; and if so, in the same limb, and how many times? Even an approximate determination as to the precise manner in which a fracture has been produced is often extremely difficult to reach. It is certainly marvelous and often inexplicable how one may at times fall 50 feet or more and entirely escape injury, while another may fall one-third the distance, or less, and sustain multiple and grave fractures. But there are fractures which have quite absolute and unique histories of their own, which, when we are familiar with them, will not deceive us.

*Typical fractures.*—Fractures near the epiphyseal end, at the radio-carpal articulation or the tibio-tarsal articulation, are usually the outcome of indirect violence. Fractures much removed above these positions are generally the outcome of force directly applied. This is notoriously the case in fractures of any part of the shafts of the ulna or fibula, when uncomplicated. The diaphyseal center of the humerus, too, is seldom broken except by the application of direct force. This generally holds good with the same anatomical structure of the femur. Apophyseal fractures are, with few exceptions, the result of indirect force. The only exception to this general rule would be the elbow joint of the youth. The clavicle usually fractures in consequence of indirect violence. The body of the scapula, the pelvic bones, the carpus, tarsus, metacarpus, and phalanges fracture rarely, except through crushing force applied over them. The late Prof. Darling, of New York, used to say that one should recognize the etiological factors in broken ribs by the direction which the fragments took after injury. He taught that when the vulnerant force was applied directly over the costal convexities the ends broken off must needs penetrate the pleura and perchance damage the pulmonary organ underneath, but when the force was applied indirectly, as by antero-posterior pressure or by muscular action, then the fractured ends would press outward under the integument, when the respiratory organs would escape. As fractures of the skull constitute a unique and independent class of injuries, which in their physical qualities and clinical phenomena present characteristics peculiar to themselves, they will not be embraced in this review. Fractures of the spine possess no definite physical or

clinical characteristics. A current impression prevails that a broken back or fracture of the spine is always a very grave injury, which necessarily must entail a permanent crippling; but this is erroneous, as a general rule, as has been repeatedly demonstrated. It is only when the cord is simultaneously damaged that paralysis succeeds in consequence of the fracture. Fractures of the spine follow direct and indirect force; the latter more frequently. When they occur as a consequence of direct concussive force, the consequences are more serious. Fracture of the lingual or hyoid bone is an exceedingly rare lesion. I have never met with one in more than 3,000 fracture cases.

In modern times, since the rapid and enormous extension of the railroad, very many are crushed or maimed by the vehicles which are rolled over them. These fractures are commonly compound when the wheels roll over the limb. But there are many exceptional cases, in which the integuments are unbroken, yet the bone has sustained extensive shattering, the neural or vascular trunks being seriously damaged at the same time. The extent of damage to the limb after having been run over by car wheels will depend on many factors directly connected with the condition of the patient, but more often with the weight of the car, whether a street car or a steam railroad car, freight or passenger, whether or not it was loaded or empty, whether one or both wheels passed over the injured limb, and whether the car was in rapid or slow motion. So many cases have come under my observation in which one or both wheels have passed over a limb on a street railway without destroying its integrity or even causing a fracture, that we certainly can no longer entertain the view that an accident of this description will always irretrievably destroy the limb. In all cases in which shamming is suspected we should carefully examine the clothing and look for abrasions, ecchymoses, or discolorations of the integument. This class of accidents seldom occurs except to young and heedless children, to those physically incapacitated, or to the intoxicated.

Steam railroad injuries of the limbs constitute practically a separate class of fractures. With these are fixed sets of symptoms seldom associated with tramway accidents. There is commonly bodily and organic injury as well as the local disorganization. This former may quite overshadow the latter in importance and gravity. It is well in all these cases to determine the extent and degree of bodily injury present in all cases, if possible, at the first examination. Another element of far-reaching importance is that of a psychological character, the element of fright and of nervous shock. It has long been noticed that when those injured on railroads are employed on them, the extent of shock is not so great as when the same degree of traumatism is borne by a passenger. A limb run completely over by the car wheel on a steam railroad of a trunk line must inevitably be greatly damaged, and in the vast majority of cases completely destroyed. I have no recollection of having ever seen a limb survive which has been rolled over by the wheel of one of those freight or passenger cars, though there are records of such injuries wherein the limb has escaped destruction. It is almost needless to say that in all this class of injuries the fractures are compound. But it is well to note that the living integument is a very tough tissue; and hence in many, while there may be but a small opening in the integument, the inclosed bone and muscle are ground to a pulp, while the main arterial trunks and nerves are completely torn through.

#### FRACTURE-DISLOCATIONS.

The etiology of fracture-dislocations is generally definite and simple. With the exception of machinery accidents, they are seldom if ever induced except by indirect force; but at the elbow they more commonly are occasioned through violence acting immediately over the seat of injury. The causative factors in a Colles's or a Pott's fracture are so well understood and so constant that we would regard

with suspicion a fracture belonging to either of these in which it was alleged that it had been induced by a blow or by being run over. We will very rarely, if ever, induce a dislocation by any measures which we will employ in treating a fracture; but, unhappily, the converse is not the case. The humerus is often fractured below the surgical neck in the effort to reduce a dislocation of the shoulder. Two such accidents have occurred in my practice; one in a man and one in a woman. Many years ago I saw this accident happen in Bellevue Hospital while Dr. Frank Hamilton was assisting in the reduction of the joint. In both of my cases the bones remained out of their socket. No case has come to my knowledge in which a civil action has been brought for damages after this complication has followed; and it is difficult to conceive how ground for action could be reached when ordinary precautions are observed.

#### FRACTURES RESULTING FROM THE ATTEMPTED LIBERATION OF ANCHYLOSED JOINTS.

All anchyloses of joints are attended with an atrophy of the muscles which act on them and the bone substance of the shafts on the proximal end of the immobilized joint. It is quite impossible in many cases to determine the nature, extent, or situation of the pathological conditions which cause the ankylosis. It may be osseous or ligamentous, intrinsic; or it may be, what is most common in my experience, caused by extensive adhesions between the muscle sheaths with degeneration, contraction, or shortening of all the flexor muscles, extrinsic. If the case be not carefully studied, its pathology fully appreciated, and force skillfully and judiciously applied, much harm may follow manipulation. The femur has fractured twice in my hands in trying to break up an ankylosis of the knee joint. In attempting the same procedure on two others I have fractured both patellæ, much to the increased strength of the limbs. In many types of knee-joint ankylosis this is a procedure which is rather a valuable therapeutic measure than a source of ultimate detriment to the limb. In fracture of a femur, when every possible precaution was employed, particularly were complications to follow the accident, the question of damages might be raised.

#### FORENSIC CONSIDERATIONS IN THE ETIOLOGY OF FRACTURE.

On a superficial view of the subject one might assume that the surgeon had performed his part and fully discharged his duties in a case of fracture when fair structural and functional restoration had been secured without deformity. As far as one's legal obligations are concerned, this view is correct. But, in this country and in our times, when the sanctity of an oath is indifferently regarded by many, when perjury is rarely punished, and when so many maintain themselves by resort to sharp practices, it behooves the medical attendant in the interests of justice and science to examine with great caution every case of fracture or dislocation in which he has the slightest suspicion of the perpetration of fraud. A designing person may, through a ruse, go through the farce of being injured. He may have had an old dislocation, an ununited fracture, or a deformity which may present many of the characters of an impacted fracture. Now, with a few well-coached, pliant witnesses and the testimony of a reputable practitioner, the plaintiff is in a fair way for recovering heavy damages if neglect of an individual or a corporation can be proven. It is, then, of cardinal importance that the causation be clearly established in every case of fracture which comes under our observation. But how can we determine the recency or proximate causes of a fracture in most cases?

#### MEANS FOR ELUCIDATING CAUSATION.

This may be accomplished by rigorous examination of our patient, both as to his general condition and as to the local condition of the parts. In every case of a fracture or dislocation, if seen within twenty-four hours, well-marked constitu-

tional disturbances are usually present. As a general rule, with very few exceptions, in all cases of fracture of the long-bone shafts or dislocation of the major articulations, the body sustains, simultaneously, more or less shock. But should evidence of this be absent, or present in only a mild degree, local phenomena of reactory inflammation are visible. There is immediately after injury a pallor of the features; the general integument is pale and anæmic; the pulse is weakened and quickened; and if we observe the patient cautiously we will notice well-marked diminution in bodily strength. Following immediately after injury constitutional symptoms are more marked and accentuated. Now we should find evidence of surgical fever, elevation of temperature, with a full pulse, and an expression of the countenance which bespeaks bodily suffering. This latter in simple fracture is not always well defined.

#### LOCAL CONDITION OF THE PARTS.

The age of a fracture, whether recent or of long existence, can be ordinarily definitely determined by local conditions. The same will apply to dislocations. We will first note the state of integument, as to whether it is bruised or lacerated; whether we have evidence of sanguineous extravasation or tumefaction. Abnormal mobility of the fragments, with crepitation, are unmistakable evidences of fracture. Mobility in itself gives us but little information with respect to acuteness or chronicity of a fracture. For we may see it in an old fracture and in the recent fracture it may be wholly wanting. But bony crepitus is an unerring monitor. No tongue or pen can adequately describe the tangible qualities of this sensation. That harsh grating sensation which it transmits to the hand has no parallel in any physical phenomena whatever. It must be felt repeatedly to be fully appreciated. But when we once are acquainted with it, it can never deceive us. In old fractures or dislocations, atrophic and arthropathic changes, when carefully sought for, will stamp the true character of the lesion. Difficulty is only encountered in very fat individuals, mostly females, in whom the joints and bone shafts are often covered in by dense layers of adipose tissue.

#### ON THE MANNER IN WHICH A FRACTURE HAS BEEN SUSTAINED.

Has the bone been fractured by muscular action or by extrinsic violence, by direct or by indirect force? A fracture of bone from muscular action alone can occur rarely, except when the elements of the bone are the seat of pathological changes, as cancer or osteomalacia, etc. The only exception to this, perhaps, is in the case of the patella. But, from my own observation, I am inclined to believe that fracture is a lesion rarely attributable to muscular action. In about 30 cases of this type which have been treated by me in none was fracture wholly attributable to this cause, but rather to indirect violence. A fracture of a shaft from muscular action I have never met. In a general way we know that in the great majority of the most common types of fracture they have a definite etiology.

We know that Colles's fracture at the wrist and Potts's fracture of the ankle are always attributable to indirect force, as are also many fractures of the lower end of the tibia, while fracture of the femur, the fibula, and the ulna most commonly occur in consequence of direct violence. This is generally true, too, of those fractures which involve the upper third of the tibia or fibula, when separately fractured, the radius, and ulna, and the humerus in any of its segments. The shafts of bone are sometimes fractured *in utero*, we are informed, but this must be a rare accident. I have never seen such a case or seen a report of one in the current literature of surgery within my recollection. Indeed, with the osseous structures yet in a cartilaginous condition, it is difficult to conceive the possibility of such a lesion except in the latter stages of pregnancy, when should such a traumatism be borne by the uterus through violence applied over it, it seems inevitable that life itself must be

seriously imperiled. It is very probable that such few cases as have been reported were those in which the bones were broken in their passage through the canal of emergence at the time of delivery. Fractures of the femur during delivery are not uncommon, but they almost invariably promptly unite and leave no trace of deformity.

#### FRACTURE OF BONE IN MORTAL INJURIES.

The question as to the precise date of fractures which have been found post-mortem has occupied an important position in many medico-legal cases, but as they pertain, in the greater number, to skull injuries, an extensive consideration of them is not now necessary. Ogston (*Forensic Medicine*, p. 5141) alleges that "the presence or absence of a blood-clot in a fracture detected post-mortem is of no definite value in determining whether a bone was fractured before or after death," and says that "the only real test is the presence of reparative processes;" and that "this, only, can the medical jurist rely on." He adds, though, that a clot found between the ends of a fractured shaft is decisive proof that it was of an ante-mortem character. In this, however, Casper does not concur. Devergie (*Médecine-Légale*, Vol. II, p. 101) tells us that every shaft of bone fractured completely after adult years are attained; results in a diminution of the volume of the bone, which, in the living or the dead, is easily appreciable in thin subjects, but in fat subjects, particularly women, it is not easily detected. In the absence of a well-defined callus, this, he says, is important to remember. In concluding this part on the etiology of fracture from a forensic standpoint it is well to always determine, if possible, by a thorough scrutiny into the patient's or subject's history, whether he had a predisposition to fracture, had a preternatural fragility of the bones, or had previous fracture. On inquiry in fracture cases in my hospital service, many instances have come to my knowledge in which the patient has previously fractured other bones of the skeleton. Many have come under my care in which the most trifling sort of force had broken the bone. Ogston (*loc. cit.*, p. 210, Vol. II) cites the case of a carter who, in jumping from the shaft of his cart, fractured both of the femora in their centers. He mentions another case, which ended mortally, in which but a slight blow on the shoulder so shivered and shattered the head of the humerus and upper third of its shaft that the man succumbed to it. On autopsy it was found that the bone was composed wholly of a friable, spongy tissue, with only a thin shell of compact tissue to enclose it. In all these cases, on examination, we should sedulously inquire into the patient's general condition, with a view of learning if he were in any way invalided by a preëxisting local or constitutional infirmity, as ankylosis, the wearing of an artificial limb, rheumatism, or paralysis, or any other infirmity which would in any manner interfere with locomotion, as these should each and all be regarded as indirect but important factors in the etiology of many fractures and other injuries.

#### DIAGNOSIS.

As previously stated, it is of fundamental importance that a correct diagnosis be reached, if possible, on the first visit. Many a medical attendant has come to grief through neglect to rigorously observe this rule. It is true that there are often many obstacles in the way at one's first visit. First, the fracture, if recent and close to an articulation, may be of such a character as to defy detection, and if many hours have elapsed before it is seen inflammatory changes, with intumescence of the adjacent parts, may be so great as to quite completely mask the indubitable symptoms. The bone may have been fractured transversely without any displacement, and the temporary muscular spasm, always present when reactionary inflammation has set in, holds the fragments in firm apposition. It may be said that with many fractures their recognition is indispensable rather from a medico-

legal standpoint than with respect to treatment. Many fractures, from their situation, are extremely difficult to recognize without the aid of an anæsthetic and one or more assistants. This is particularly true of the proximal end of the femur and fractures which involve the elbow joint. A fracture of the anatomical neck of the humerus may be mistaken for a dislocation if great care is not exercised. There are types of luxation and subluxation of the radio-carpal articulation which on superficial examination present some of the characteristics of fracture, and *vice versa*. Secondly, we may encounter impediments from the patient and the environment. The patient, if a female, may, through a sense of modesty, be reluctant to permit the medical attendant to expose her in his examination. She may allege that she has but a sprain, and that such examination is not necessary. Her word may be unwisely taken and an examination not insisted on. Such a case occurred in New York very recently. The patient, an actress, had been kicked by her husband in an altercation, the blows falling on the leg and knee joint. Very great pain following, a neighboring physician was called in, who hastily examined her limb under her garments. He prescribed a liniment and made light of the case. Later, another physician was called, who detected a fracture of the patella with some inches of separation of the fragments. I was invited in to verify the diagnosis. A civil action was instituted against the first medical attendant, through which a verdict was found for the plaintiff. One may be called late in the night, far away from associate medical aid, or to one wholly unable or unwilling to pay the expenses of a consultation. Our patient may be hypersensitive, intoxicated, boisterous, or unmanageable, but the law holds us equally responsible for all. In large cities and populous towns there is some relief for us in these cases by sending them to a hospital, but in small villages and scattered country sections we generally can not shift the responsibility. Most of our mistakes in fracture diagnoses arise from haste or an imperfect knowledge of the anatomical and physical qualities of the lesion. A few years ago a vigorous young laborer came to me to attend him for a fractured clavicle. He had a few hours before been at one of our most noted dispensaries, and the shoulder was already firmly adjusted by a modified Sayre's dressing and enveloped in several deep layers of a copious dressing. But he had great pain and demanded a redressing. I sent him back to the dispensary from whence he came, reminding him that most public dispensaries are schools for instruction and that what he got for nothing must be generally valued accordingly. In a little while he returned again, begging me to examine the dis-trained joint. He had been at the dispensary, but besides nicking the edges of the dressings with scissors nothing had been done. On removal of all the dressings, I discovered no injury of any description. We can well imagine the consequences to a healthy limb and articulation in such a harness for six or eight weeks. An elderly woman, out marketing one winter night, slipped on the curb-stone of a sidewalk and was unable to rise. An ambulance was called, and she was entered in the surgical ward of one of our principal hospitals. The house staff, wearied after a heavy afternoon clinic, made a hurried examination, pronounced her case one of fracture of the head of the femur, and put the limb up in a Buck's extension apparatus. She was informed that she must keep the bed for six or eight weeks and that she would be lame for the remainder of her life. Her friends sought her out, and, in spite of the protests of the doctors, brought her home the same night. At about midnight I was called, and on examination discovered that there was no fracture of any kind, but a dislocation of the head of the femur backward on to the dorsum ili. With the employment of a strong clothesline and three strong young men, boarders in the house, I was able to readily reduce the displaced bone. In two weeks she was about as usual with scarcely a perceptible limp. In doubtful cases of fracture we should always insist on a consultation or advise the patient of our doubt. Then, should

deformity occur, we are not responsible for it or the error through which it exists. Surgeons and practitioners are sometimes called in after a case has been under the care of another practitioner, and in which possibly it may be alleged that there was no fracture, but that the practitioner had tried to "make a case" of it with a view of extorting a fee or aiding the patient to secure damages for a spurious injury.

In this connection it is important to inquire: Are there any physical evidences during life by which we can determine whether or not there has been a fracture sustained when we can only examine the limb one or more weeks after the alleged injury? In the case of a fracture of the femur or humerus in an adult, it is my conviction that imposition is rarely possible. But in any simple fracture in a growing child, or one which involves the tibia, fibula, radius, or ulna of an adult, after the first week there are no means known to art by which we can determine this question with definite certainty. It has long been known that bones, like the soft parts, unite by two processes, primary union and secondary union. In the latter we always find a callus; in the former not necessarily. This has been repeatedly demonstrated in my own practice in cases in and out of hospital. Within the past year a case came under my observation in which a gentleman had injured his right leg, and the question arose as to whether or not he had a fracture. He had been injured nine days before I saw him. The attending physician had called in one of our best-known surgeons, who decided that he had a fracture in the lower third of his leg. At my request the plaster dressings were removed in order that I might examine the under limb. The patient persistently protested that he had no fracture. I could certainly discover no positive evidences of any; but nevertheless, knowing the respectable character and high attainments of the former consultant, besides bearing in mind those occasional cases of primary union, practically non-calloused fractures, advised the family that there had been a fracture and recommended the removal of the plaster cast, now rendered unnecessary. In a simple fracture case in a young man, in the event of a litigation over a case, the defendant is often quite at the mercy of the medical attendant. Therefore the practitioner who would uphold the honor of his profession and refuse to be an accomplice to a crime must exercise great caution that he does not prematurely designate a sprain a fracture, and thereby work very serious injury against an innocent party and strike at the very foundation of civilized society by committing a felony. On the contrary, he must be vigilant; that he does not designate a fracture a sprain because there is neither pain, deformity, or loss of motion. It is an humiliating admission to make, but truth and justice demand it; and hence it must be confessed that of late years many cases have come to my knowledge in which no severe bodily traumatism of any kind had been borne, in which "worked-up cases" of fracture had been pressed for no other purpose than extorting money. Those heavy accident insurance and tontine societies are great inducements to dishonesty and extortionate practices. Indeed, a case came to my knowledge within the past winter (1893) in which a physician was approached by a gentleman who had been his former patient, and informed by him that he was carrying a heavy accident policy, which would pay him \$50 per week, in the event of accident, for ten weeks, adding that he was then in straitened circumstances; and he had the audacity to ask the doctor if, for a consideration of \$50, he would splint his arm and treat him for a pretended fracture of it, so that he might raise some money from the company on a medical certificate.

#### DIAGNOSIS OF COMPLICATIONS ATTENDING FRACTURE.

It is well to remember that in most fractures resulting from violence simultaneously with the bone disorganization there is severe bodily shock, and possibly other structural organic lesions, resulting from the same influences. This is partic-

ularly true of railroad and machinery injuries. There may be a dislocation with the fracture or there may be fracture of other bones, notably of the skull or ribs. In recent times spinal shock or concussion of the spine is not infrequently said to attend as a complication of fracture. In all those serious cases, in the interest of all parties, it is an imperative duty that a minute scrutiny of the entire body be made at the primary examination or as soon as the patient is in a condition to safely bear it.

#### PROGNOSIS.

A clear conception of the causes of a fracture, with a comprehensive knowledge of its type or character, opens the way to a reasonably safe prediction as to immediate and remote results. Very often when called to attend one suffering from a broken bone we are persistently importuned by the relatives or friends of the patient for an opinion, or an assurance, as to the ultimate utility of the limb after treatment is ended. Here we must exercise great tact not to compromise ourselves by too optimistic promises, nor on the other hand by too somber insinuations to unduly discourage or alarm. To commit the former would be to leave us open to severe censure or a prosecution in the event of disappointment, and the latter might cause us the loss of the case, very much to the detriment of our doing a village or country practice. The succeeding practitioner, though perhaps fully realizing the serious character of the injury, would inspire his patient and those about him with hope, and yet hedge in such a way as to escape criticism.

Every one, from the meanest to the highest in this world, by an instinctive impulse, will invariably endeavor to minimize or conceal their infirmities, and the fractured invalid is no exception. An intimate familiarity with the clinical history and sequelæ of each individual case will usually warrant us in venturing an opinion after the fracture has been definitely recognized. We will be guided in the main by the age of the patient, the condition of general health, the nature and situation of the lesion, the absence or presence of complications, the facilities for treatment, etc. But in no case can an absolute opinion be vouchsafed, inasmuch as we know nothing about our patient's peculiarities, for a bone may fail to unite, the soft parts will not bear protracted pressure, ankylosis, shortening, deflection, wasting of the limb, gangrene, or persistent weakening in the limb may follow. These are unusual but possible sequelæ in the hands of the most experienced. No one will be rash enough to promise anything approaching perfect functional or structural restoration in a fracture which involves an articulation, or one opening into the elbow joint, an intracapsular fracture at the hip joint, a Pott's or a Colles's of the ankle or wrist joints, nor will he forget to remind his patient of a probable shortening in every type of complete femoral fracture at any age. But we may say in all cases of fracture of every description that a defective limb will always follow any line of treatment. This we may always maintain from the fact that normal, histological bone, once destroyed by either disease or trauma, is never reproduced; that the substitute which nature provides for repair, while fulfilling, in a large measure, the functions of the damaged bone shaft, is yet but a species of ossified cicatricial tissue without the vitality, strength, or resiliency of what it has replaced. We may add, too, that the younger the patient the better the prospect of functional restoration; while, on the contrary, in those at or past the meridian of life anything like perfect restitution is out of the question and permanent weakness must remain.

#### TREATMENT.

The surgical therapy of fracture has been the rock which has wrecked many an unfortunate practitioner. In past years in the United States a considerable number entered at once into active general practice with little or no practical experience in dealing with traumas. Clinical knowledge was not an essential requirement

for a medical degree, and hence, when the surgical tyro was called to his first case of a seriously complicated fracture very naturally his patient's escape from death, the loss of his limb, or a deformity might be attributed to good luck as much as to the skill and experience of his medical attendant. The law does not expect impossibilities, but it does demand of those who practice the healing art as general practitioners that they possess a reasonable knowledge of the principles which underlie it and their application; that one is acquainted with the plan of treatment called for in those cases which he assumes to manage. Of the specialist in any line of practice, whose fees are larger, much more is demanded, and his responsibility is greater. Very naturally when one has confided the management of his shattered, distorted limb to our care it is presupposed that he authorizes us, as far as is within our power, to provide every possible resource of art and science to restore the usefulness of the limb. Therefore, as many complicated and serious fractures possess unique and peculiar features, as a preliminary step of cardinal importance, in all of these cases, a consultation should be insisted on. The last thirty years has witnessed a revelation in the treatment of fractured limbs, and accordingly what were laid down as orthodox measures in the recent past will not hold now, though it must be admitted that the fundamental principles of fracture therapy yet remain. Change has been rather in the direction of detail than the adoption of new principles, except in compound fracture. Tenotomy, the extended posture with traction weights, the gypsum dressings, resection of bone as a substitute for primary amputation, all belong to modern times, none of which would have been possible without the inventions and discoveries of which these are the legitimate outcome. Accordingly it might be fairly asked if the physician had done full justice to his patient who had not utilized all the materials and facilities which modern science has rendered accessible. Right here is wherein the difficulties arise. For it might be inquired, Have all these innovations in fracture-treatment been in advance of measures formerly in vogue?

It is perfectly rational to inquire if it is a prudent plan to fix a fractured limb in any sort of immovable dressing immediately after injury.

Is the extended position, with weights or not, a gain over postural treatment, or muscular relaxation with flexion? Is plaster of Paris, in a general way, more conducive to simplicity of treatment than the older custom of segmented splinting? Is tenotomy a measure which may be generally adopted in cases of extreme rigidity and overriding of the fragments? Considerable difference of opinion prevails among the most eminent authorities at the present day on these questions, which is an evidence that none of them carry the force of dogma. It is in one's experience to now and then be called to a case in which, for many reasons, it is inexpedient to call a consultant. The patient injured is in no great pain, but it is quite impossible to say whether there is a fracture or not. Under these circumstances what should be our course of action? Or, should we encounter a case in which on consultation, no unanimity of opinion can be reached, what should be our line of conduct? In the former our interests will be better guarded by always applying some sort of temporary adjustment and watching the case until time will decide. In the latter the opinions of the majority should prevail, if there be a third party; at the same time the injured party and relatives should be candidly informed of the difference of opinion. Many practitioners have come to grief by an overconfidence in their own capacity and knowledge, by an unskillful, imperfect or hasty examination. The classical symptoms of fracture are wanting; the hypersensitive patient resists forcible manipulations, without which the definite recognition of certain fractures at certain times is utterly impossible. The patient will vehemently proclaim that he has no fracture, because "he can move his fingers or toes." A simple lotion is perhaps prescribed and the case dismissed. Possibly nothing more is heard from the case until the first medical

attendant is served with a notice of a suit; when abundant expert and other testimony is forthcoming to incriminate him for the neglect through which the patient suffered in consequence of unskilled, protracted treatment, or perhaps now he has a deformed limb. Malpractice essentially consists of two phases. First, the passive, in which one's course is not sustained by general authority. Second, when those measures in treatment are omitted which might have approximated to secure perfection in results. Very naturally those fractures which lie close to or involve the joints, and those which engage the major shafts, are the class which most often are attended with unsatisfactory results; and hence the subject of malpractice suits. Fractures when improperly treated, or when they occur in patients of unsound health, may terminate in (a) non-union; (b) deformity; (c) ankylosis; (d) muscular atrophy; (e) shortening, or (f) gangrene.

*Non-union.*—There are no means known to art by which we can predict non-union or prevent it in many cases; hence, we can not be censured for failure of union when our treatment has been on the right lines.

*Deformity.*—While, as a rule, particularly in the young, deformity can and should be prevented, in the adult, in certain types of fracture, its suppression is often quite impossible.

*Ankylosis.*—Muscular ankylosis is a general sequence of all fractures, and shortly disappears. Arthritic ankylosis is the phase which most commonly disables the injured and leads to lawsuits. It is well to bear in mind that in even the most aggravated types of this, use of the limb and time practically overcome it; more so, it is true, in some joints than in others.

*Muscular atrophy.*—Atrophic changes in the soft parts follow all fractures. But it is only when muscular wasting is persistent and permanent that complaint is heard. But it must be a very rare event, as I have never seen a case of that exaggerated type of trophic destruction of muscle mentioned in the text-books. As acute temporary atrophy is always a curable affection after fracture, it is quite inconceivable how its presence could be made the pretext for litigation.

*Shortening.*—Moderate shortening is a usual event in many fractures; hence it is only when the reduction in length is excessive that it can afford a pretext for damages, and even then, with young, restive patients, or those ungovernable to treatment, no fault can attach to the medical attendant.

*Gangrene.*—But few cases of gangrene have come under my care in fracture cases; but five, as nearly as I can remember, in all. It must be admitted that it occurred through too tight bandaging. With the exception of one, it occurred under the gypsum bandage. In three the limbs had to be sacrificed. This is an accident which, while the most deplorable, is fortunately the most rare. My impression is that a limb is seldom lost in a simple fracture from gangrene or asphyxiation of the tissues except through ignorance or carelessness on the part of the medical attendant. In considering the treatment of fracture from a forensic standpoint, a regional division of the body may somewhat simplify its study.

#### THE UPPER EXTREMITIES.

*Shoulder joint.*—Fractures which involve the anatomical neck of the humerus have been mistaken for dislocation. The epiphyseal disk sinks under the deltoid, and the shaft is greatly displaced by muscular action. A violent blow on the shoulder may paralyze the arm, occasion a fracture or dislocation. Only a most careful examination will always enable one to differentiate in this event. In any case, if in doubt, a consultation should be requested and an adjustment applied. Civil actions seldom arise in consequence of fracture through the center of this humeral shaft, but as we approach the insertion of the digital muscles and the anchyloid ridges the case is different.

*Elbow joint.*—As the elbow joint is a complicated articulation, any fracture which extends through the condyles and opens the humero-ulnar articulation may be serious in its consequences as far as the future flexibility and strength of the joint are concerned. A wide difference of opinion yet prevails in the details of treatment of this lesion, so that there is a loophole for escape in the event of suit. Some authors recommend the straight position, the arm extended; others want it flexed. Again, one would have passive motion commenced early; others would have it begun only after union is effected.

*Wrist joint.*—As fractures which occupy the middle of the shafts of the radius and ulna usually unite well under ordinary treatment with the application of general principles, those which sunder the bone near the radio-carpal articulation may be now considered. It can not be said that there is a very wide diversity of opinion in the treatment of a typical Colles's fracture; probably for the reason that in spite of any line of treatment adopted more or less impairment in motion, deformity, and ankylosis remain. This was my position in an essay read last October before the New York State Medical Association. But issue was taken with me, and some went so far as to affirm that by an appropriate therapy good results should be always secured. Valentine Mott, writing twenty-five years ago on this, said in a communication which was used as testimony in court in a malpractice case (McClelland, on Malpractice, p. 203), "fractures of the radius anywhere from 2 to 3 inches of the wrist joint, even when treated by eminent surgeons, are often very difficult of management so as to avoid all deformity; indeed, more or less deformity may occur under the treatment of the most eminent." Nevertheless, of all joints in the body there is none, perhaps, in which good or indifferent results are more dependent on treatment in fracture above it than this. Not that we can make it perfect, but appropriate treatment will avert many unpleasant consequences.

#### LOWER EXTREMITY.

*Fractures, intra and extra capsular, at the hip joint.*—Intracapsular fractures at the hip, as they mostly occur in the old and seldom unite, are not often the subject of civil actions for malpractice. The fragments rarely unite, not because there is any good anatomical reason for failure in this direction, but because it is impossible to rigidly confine the patients in the dorsal decubitus. Extracapsular fractures are uncommon at the hip, and are usually amenable to ordinary treatment. The battleground has been in cases of fracture of the shaft of the femur. The femur is a difficult bone to manage in fracture. Its principal muscular envelopes hold the distal fragment in a vicious grip, which is only overcome when dangerous pressure is exercised on the soft parts. Can we secure union here without shortening? Mott again speaks on this subject<sup>1</sup> (*ibid.*), and says that "more or less shortening is uniformly the result after fracture of the thigh under the most fortunate circumstances." On the same occasion Dr. Alfred C. Post stated that "the injury of the soft parts would interfere with extension of the limb," and that he had "personal knowledge of two cases in which the attempt to make extension and counter extension resulted in mortification," and that "the thighs had to be amputated." Mr. C. B. Keetley, of London, in a recent able contribution ("On the Prevention of Shortening and Other Forms of Malunion After Fracture," London Lancet, June 10, 1893), says:

It is well known that surgeons of great eminence and high character have claimed uniform success in treating fractures of the femur without resultant shortening; but I think the trenchant criticism of these claims, given in Hamilton's Treatise on Fractures, that they have not been made out, and are not to be trusted, etc., is just. \* \* \* I will venture to take it for granted that serious shortening occasionally follows fracture of the femur, treated however carefully by all methods hitherto described.

<sup>1</sup> ——— vs. Oatman.

Of late years fracture of the femur has been chiefly treated either by the gypsum cast or by extension in the United States. Dr. Lewis A. Sayre was a warm partisan of the plaster dressing, claiming almost uniform good results without shortening. He lays the law down as to the principles of extension, fixation, etc., which are all very well in theory, and long known as fundamental in surgery, but which are utterly impracticable in the majority of cases. Dr. Frederick Hyde reported 308 cases of fracture of the femur, which were treated in Bellevue Hospital from 1868 to 1873, inclusive, in which the average shortening in all cases (the perfect and others) was half an inch.

In the years 1872 and 1873 the late Frank Hamilton and Lewis A. Sayre reported their results separately, Sayre employing plaster dressing with almost no shortening, if any. Hamilton's cases were treated with Buck's extension. He confessed to having shortening as a rule. Sayre's tables bear the traces of an enthusiast, for in the column of results there is an apparent evasiveness of detail as to deformity or shortening, while the successes are submitted in detail. (A Record of Fractures Treated at Bellevue Hospital with the Plaster Apparatus, from April, 1871, to April, 1872.) Dr. F. Hamilton's tables of results in fracture treatment, revised and completed by McClelland, presented to the American Medical Association in 1856, though a unique and exhaustive résumé of the subject, is of little or no statistical value, for the reason that they are drawn from widely scattered sources and are necessarily inaccurate, because of the difference of interpretation in analysis of results. For instance, one author may affirm that he has a perfect result, after the fracture of a femoral shaft, if his patient showed no lameness. On the contrary, another would fail to realize perfection unless perfect length were restored. Now, Velpeau taught that there is never any limping when the shortening does not exceed three-fourths of an inch. (Leçons sur Des Fractures, p. 211.) Liston said that it should be borne in mind that there have been fractured limbs released from splintings at the proper time, of the proper length, free from deformity, which have, nevertheless, soon after become bent and shortened. (Liston's Elements of Surgery, 555.) It may then be laid down as a rule that shortening is the common result after fracture of the femoral shaft, and full restoration of length the rare exception.

*Fractures at the ankle joint.*—Simple fracture of the shaft of the tibia or fibula, or both, is of common occurrence; and except in unusual instances, from censurable neglect generally, does it become the subject of malpractice suits. But those oblique fractures in the lower third of the tibia and that type designated Pott's are difficult to treat, and are often followed by deformity and a defective joint action, regardless as to how they are managed. I have never seen a genuine Pott's fracture so treated but some deformity remained. Percival Pott himself, as well as Dupuytren, both distinguished authorities on fracture, regarded that fracture luxation, with fracture of the internal malleolus at the lower third of the fibula, with extensive laceration of ligament and tendon, and dislocation, as always a very serious affair. Certainly in this, as in all other types of fracture, as a general rule, the results will be commensurate with the skilled attention bestowed.

#### THE QUESTION OF DRESSINGS AND MECHANICAL ADJUSTMENT.

Of late years a considerable number of practitioners have had to sustain malpractice suits in which the dominant question at issue has had reference to the materials employed and the time at which definite adjustment is made. Since the introduction of plaster of Paris the treatment of fracture has undergone a revolution. That it has greatly simplified its treatment goes without saying; but that its employment is safe and the results are as good as treatment by the older methods is not by any means yet settled. My own experience entirely coincides with that of a modern author, and I am in entire accord with his views. McClel-

land (Malpractice Suits, p. 176) says: "Plaster of Paris as a primary dressing requires large experience, inasmuch as it is likely to be followed by the same bad results that so frequently follow the use of the primary or initial bandage. It is not yet the *sine qua non* so long and anxiously looked for by surgeons in the treatment of fracture." The other forms of so-called immovable dressings are just as objectionable for the same reasons. As a secondary dressing after the primary is removed, and as a dressing for compound fracture, it is highly satisfactory; and for hospital practice, where it can be seen every few moments, and be under the eye of the house surgeon or a nurse familiar with these injuries, it may be employed with good results. The surgeon who applies it to his patient 10 or 12 miles away does so at great peril to his patient and himself."

Dr. Lewis A. Sayre was a warm advocate of primary plaster dressings. In my own time of internship, in 1875 and 1876, it was the routine practice to envelop the freshly fractured bone at once, on entrance, in wet plaster bandage. It was a vicious, cruel, and destructive practice, but it was all the rage then, and he who neglected to employ it thuswise was an "old fogey," or was not up in progress. But gangrene so commonly followed, or ankylosis, shortening, and deformity, that its primary employment is generally discarded now, though the theory died hard before surgeons would open their eyes to its dangers. Plaster of Paris brought with it a change in the attitude of the limb and introduced a new principle of treatment into fractures. With its employment the limb must be extended and the joints locked immovably. The principle of muscular relaxation and postural methods were necessarily cast aside. The old-time fracture box was thrown out as a relic of barbarism. But, with these innovations in simple fracture treatment, it yet remains an open question whether they have constituted real progress or not. Every individual case of fracture constitutes an entity in itself; therefore to attempt to generalize any form of treatment as applicable to all is worse than folly. Hence, with the exception of very aggravated and unusual cases, no blame should attach in a given case because certain special details in treatment were not carried out by the medical attendant. The treatment of fracture in respect to the time of "setting" the bone has been radically changed of late years. In the beginning of the present century, and for some time after, it was the common custom to delay splinting the limb for some few days after fracture. John Hunter taught that splints should not be applied until after all inflammation had subsided (Hunter's Surgical Lessons, p. 177), while Chelins advised a primary, fixed dressing only in oblique fractures and those which involve the collar bone, and directed that for the first three or four days nothing should be done except to lay the limb on a pillow in such a position as will give the patient the greatest ease and soothe the irritable muscles (Chelins, p. 555). I have recently set forth in a brochure published (At What Date Should Permanent Dressing Be Applied after Fracture; Practice, Richmond, Va., April, 1893) my views on this question and cited cases which have come to my knowledge in which suits for malpractice have been instituted; in one set in which it was alleged permanent fixtures had been applied too early; in another in which judgment had been given because the medical attendant had been tardy in applying rigid fixtures. The fact is that at the present time the tendency is to apply permanent fixtures too indiscriminately as a primary measure. Indeed, there can be scarcely a doubt but that the most disastrous consequences we ever see in fracture often ensue from rigid, unyielding dressings over the freshly mutilated parts prematurely applied. It is better, then, to err on the side of safety; wait until the circulation is reestablished and all violent inflammatory reaction is past; then so adjust the limb that the patient will secure the greatest comfort with the best promise of good results. If the doctrine of rigid immobilization would hold, there might be some justification for the immediate adjustment in a permanent fixture of all simple fractures; but it will not,

for anyone of experience knows that moderate intermittent motion in a fractured limb often rather favors than hinders osseous consolidation. It is a mooted question among many of our most eminent authorities whether in many types of fracture any sort of splinting is ever of any service, as in intracapsular fracture at the hip joint and impacted Colles's fracture in old people. From a forensic standpoint it must necessarily be an extremely difficult question to answer in many instances as to just what is the most judicious line of treatment to adopt, which is censurable or which is not, particularly when one must decide without having seen the case as an expert.

#### TREATMENT IN COMPOUND FRACTURES.

So great and rapid have been the advances in the treatment of compound fracture within the last two decades that, when properly managed, many lives and limbs are spared which were formerly sacrificed, distortions obviated, inflammation, necrosis, and mortification prevented. Painless and aseptic, skillful manipulation of mangled parts, a more intimate knowledge of pathological changes, with the mechanical aids and perfected dressings at our command, have each and all contributed toward bringing the treatment of compound fractures to well-nigh a state of perfection. Any tyro of common sense may treat a simple fracture. Handy old men have been efficient "bone-setters," but for the intelligent management of compound fractures at the present day special skill is imperative. Many a smashed, temporarily asphyxiated limb, which in years gone by would be promptly condemned to the amputating knife, must now be saved. The medical attendant should not only be familiar with all the principles of treatment of these cases on modern lines, but he should also be ready to do such osteoplastic operations as the case may require during the progress of the cure. To do anything less is an injustice to one's patient and leaves us open to a civil action. Statistics tell us that the mortality in the treatment of compound fractures under modern methods has fallen from 60 to less than 5 per cent. It may be added that the proportion of limbs spared and made useful is equally large. And along with all this, one of the most salutary and beneficent features is the enormous diminution of human suffering. The responsibilities of the surgeon in serious compound fractures are always great; therefore, to do full justice to his patient and protect himself, he must redouble his vigilance and throw around his patient and himself such safeguards as will redound to the welfare of both.

In the foregoing notes extensive reference to the historical part of the subject has generally been purposely omitted, my aim having been rather to present what would seem to be the safest lines on which the whole question of fracture should be regarded when the question of malpractice may arise and the means which one should employ to protect himself in all cases of this description. There are fractures of many other bones of the body which often entail lawsuits, particularly those of the skull, clavicle, and ribs; but in the present brief notes it was found impracticable to incorporate them. Members of our profession, as a rule, should discourage as far as possible suits for malpractice. Without the connivance and encouragement of practitioners their successful prosecution is rarely possible. So that, unless a case presents evidence of positive criminal carelessness or total want of skill, we should not give them our support.

## EXPERT AND OPINION EVIDENCE.

By CLARK BELL, Esq., of the New York Bar.

There has been so much confusion and conflict in expert testimony; so much discussion and difference of opinion as to the true province of the medical expert, especially in homicidal cases, and the subject has become so involved in the minds of medico-legal jurists that I have felt that a carefully prepared and reliable statement of the present state of the law in America and in England would be of value to both professions of law and medicine. The completely equipped medico-legal jurist, whether a lawyer or a medical man, should be advised of the state of the law upon the particular specialty upon which he is to be examined, concerning which he is to give testimony, and I have prepared with care the presentation of the law as it now exists, with a very full reference to the authorities upon each branch examined, for the use of lawyers, medical men, and medico-legal jurists generally, who are called as experts or to give expert opinions or medical evidence, and to enable them to clearly understand and reliably ascertain the real issues in such cases and the admissibility and bearing of expert testimony upon them. In editing the American edition of Taylor's Medical Jurisprudence last year I gave to both professions upon this and similar medico-legal questions the authorities in our country and in England upon which the law stands, and I draw upon my labors in this branch of that work for much of the present paper.

## I.—EXPERTS.

An expert is one who has made the subject upon which he gives his opinion a matter of particular study, practice, or observation, and he must have a particular and special knowledge upon the subject concerning which he testifies. (Page *v. Parker*, 40 N. H., 59; *Jones v. Tucker*, 41 N. H., 134; *Heald v. Thing*, 45 Me., 392; *Mobile Life Ins. Co. v. Walker*, 58 Ala., 290; *Slater v. Wilcox*, Barb. N. Y., 608; *Dole v. Johnson*, 50 N. H., 454; *Hyde v. Woolfolk*, 1 Iowa, 159; *State v. Phair*, 48 Vt., 366; *Nelson v. Sun Mutual Ins. Co.*, 71 N. Y., 453-460; *Vander Denckl v. Helluson*, 8 M. G. & S., 812; *Bird v. State*, 21 Gratt. (Va.), 800; *Dickinson v. Fitchburgh*, 13 Gray (Mass.), 546, 553; *Nelson v. Johnson*, 18 Ind., 334; *Estate of Toomes*, 54 Cal., 514; *Travis v. Brown*, 43 Pa. St., 12; *Buffum v. Harris*, 5 R. I., 250.)

## II.—EXPERT EVIDENCE.

1. Expert evidence is that testimony given by one expert and specially skilled in the subject to which it relates or is applicable; concerning information beyond the range of ordinary observation.

2. The general rule of law is that witnesses must testify to facts and not to opinions. (*Clark v. Fisher*, 1 Paige (N. Y.), 171; s. c. Am. Dec., 402; *Neilson v. Chicago, etc., R. Co.*, 59 Wis., 516; *Watson v. Milwaukee, etc., R. Co.*, 57 Wis., 332; *McNiel v. Davidson*, 37 Ind., 336; *Pindar v. Kings Co. Fire Ins. Co.*, 36 N. Y., 648; *Bass Furnace Co. v. Glasscock*, 82 Ala., 452; *Heath v. Slocum*, 115 Pa. St., 549; Amer. and Eng. Enc. of Law, Vol. 7, p. 495, note 1.)

a. The witness must only state facts and not draw conclusions or inferences from facts. (*Luning v. State*, 2 Pin. (Wis.), 215; s. c. Chand. (Wis.), 178; s. c. 2 Pin. (Wis.), 285; s. c. 1 Chand. (Wis.), 264; *Abbott v. People*, 86 N. Y., 460; *People v. Murphy*, 101 N. Y., 126; *Sloan v. N. Y. Cen. R. Co.*, 45 N. Y., 125; *Campbell v. State*, 10 Tex. Ct. of Appeals, 560.)

b. It has been held that to allow witnesses to draw conclusions from facts or inferences is to usurp the province of the court or jury, and is illegal. (*Booth v. Cleveland Rolling Mill Co.*, 74 N. Y., 15; s. c. 11 Hun, 278; *Allen v. Stout*, 51 N. Y., 668; *Campbell v. State*, 10 Texas App., 560; *In re Sale of Infant Land*, 6 C. C. Greene (N. J.), 92.)

## III.—EXCEPTIONS TO THE GENERAL RULE.

While these are the general rules of law, there are exceptions where the opinions of skilled experts may be taken as before stated (*supra*, 3 a-b).

a. In cases of necessity, where it is impossible to make the court and jury understand the matter in controversy without it.

b. To inform the court or jury as to physical laws or phenomena, which practice dates back to the old Roman law. (L. 8, Sec. 1, XL; L. 3, Sec. 4, XI 6. And this has been followed in France: 2 Beck's Med. Juris., 896. And in England in analogous cases: 9 Henry, 7, 16; 7 Henry, 6, 11; *Buckley v. Rice*, 1 Plow, 125.)

c. To show the results of voluminous facts collated by a competent person who has examined and is shown to be competent to make the deductions. (*Burton v. Driggs*, 20 Wall. (U. S.), 125; *Von Sachs v. Kretz*, 72 N. Y., 548; s. c. 10 Hun (N. Y.), 95.)

## IV.—OPINION AND OPINION EVIDENCE.

Opinion evidence is the conclusions or opinions of witnesses concerning propositions based upon ascertained or supposed facts, by one who has had superior opportunities and greater knowledge than the ordinary person or witness to judge of the subject-matter of the inquiry, and who, by reason of his especial knowledge of and experience with the subject, is believed to be capable of arriving at a better and more reliable conclusion and judgment, from facts within his own knowledge, concerning the questions involved in the inquiry or controversy.

a. Any witness not an expert, who personally knows the facts, may give an opinion in a matter regarding skill, after having stated the facts on which he bases his opinion; or as to matters with which he is especially acquainted, or has personal or peculiar knowledge, but which cannot be exactly or specifically described to the court or jury. (*Indianapolis v. Huffer*, 30 Ind., 235; *Doe v. Reagan*, 5 Blackf. (Ind.), 217; s. c. 33 Am. Dec., 466; *Wilkinson v. Moseley*, 30 Ala., 562; *S. & N. Ala. R. Co. v. McLeudon*, 63 Ala., 266; *Chic., etc., R. Co. v. George*, 19 Ill., 510; *Willis v. Quimby*, 11 Fost. (N. H.), 485; *Elliott v. Van Buren*, 33 Mich., 49; s. c. 20 Am. Rep., 668; *Culver v. Dwight*, 6 Gray (Mass.), 444; *Irish v. Smith*, 8 S. & R. Co. (Pa.), 537; *Cole v. State*, 75 Ind., 511; *Wharton's Evidence*, section 512; *Stephen's Evidence*, 103; *Porter v. Requonnoe, etc., Co.*, 17 Conn., 249; *Curtis v. Chic. R. R. Co.*, 18 Wis., 312; *Bennett v. Mehan*, 83 Ind., 566; *Ceru v. Doudican*, 114 Mass., 257; *State v. Folwell*, 14 Kan., 105; *Alexander v. Jonquill & Sterling*, 71 Ill., 366; *Blake v. People*, 73 N. Y., 586; *Bradley v. Salmon Falls Mfg. Co.*, 30 N. H., 487; *Ray v. State*, 50 Ala., 104; *Raisler v. Springer*, 38 Ala., 703; *Aulago Co. v. Davis*, 32 Ala., 703; *Pook v. State*, 62 Ala., 237; *State v. Babb*, 76 Mo., 501; *State v. Miller*, 53 Iowa, 84.)

b. An expert physician may testify concerning the health of a certain person whom he knows personally, or has treated, and so may any witness not an expert, as to facts within his knowledge and observation, regarding the health or physical condition of another, or whether he was or had been apparently in good health. (*Louisville, etc., R. Co. v. Wood*, 12 N. E. Rep., 572; same *Plff. v. Falery*, 104 Ind., 409; *Van Deusen v. Newcomer*, 40 Mich., 120; *Tierney v. Minneapolis, etc., R. Co.*, 24 Amer. L. Reg., 660; *Higbie v. Guardian Mut. Life Ins. Co.*, 53 N. Y., 603; *Smalley v. City of Appleton*, 35 N. W. Rep., 729; *Hanly v. Merrill*, 56 N. H., 227; *Cousin v. Sturtivant*, 117 Mass., 122; s. c. 19 Amer. Rep., 401; *Wilkinson v. Moseley*, 30 Ala., 562; *Barker v. Coleman*, 35 Ala., 221; *Carthage, etc., Co. v. —*, 102 Ind., 138; *Evans v. People*, 12 Mich., 27; *Irish v. Smith*, 8 S. & R. (Pa.), 573; *Elliott v. Van Buren*, 33 Mich., 49; s. c. 20 Amer. Rep., 668.)

c. A physician or surgeon, shown to be competent, may give his opinion as to the probable effect of wounds and injuries, after he has viewed the body and examined the wounds, and as to whether the wounds or injuries would produce

death. (*Montgomery v. Scott*, 34 Wis., 338; *Batten v. State*, 80 Ind., 394; *McDaniel v. State*, 76 Ala., 1; *Noblesville, etc., Gravel Road Co. v. Ganse*, 76 Ind., 142; *Davis v. State*, 38 Md., 15; *State v. Orenshaw*, 32 La. Ann., 406; *Armstrong v. Town of Ackley*, 71 Iowa, 76; *Rash v. State*, 61 Ala., 16; *Doolittle v. State*, 93 Ind., 272.)

d. A non-expert can not testify as to the effect of wounds or injuries.

e. Physicians shown to be qualified may testify and give opinions.

(1) As to the cause of death of a person. (*Boyle v. State*, 61 Wis., 349; *Eggler v. People*, 56 N. Y., 642; *State v. Clark*, 15 S. C., 403; *Citizens' Gas Light Co. v. O'Brien*, 118 Ill., 174; *Sullivan v. Cowen*, 93 Pa. St., 285; *Boyd v. State*, 14 Lea (Tenn.), 161; *Comin v. Piper*, 120 Mass., 188; *Eidt v. Cutler*, 127 Mass., 523; *State v. Cross*, 68 Iowa, 180.)

(2) In malpractice cases, as to whether the treatment complained of was proper. (*Quinn v. Higgins*, 63 Wis., 664; *Kay v. Thompson*, 10 Am. L. Reg. (N. Brunsw.), 594; *Boydston v. Gittner*, 3 Oregon, 118; *Williams v. Poppleton*, 3 Oregon, 139; *Wright v. Hardy*, 22 Wis., 348; *Mertz v. Detweiler*, 8 W. & S. (Pa.), 376; *Roberts v. Johnson*, 58 N. Y., 613.)

(3) In cases of rape, after an inspection and examination of the parts as to health, physical condition; and from the condition, whether there had been an actual penetration, the capacity of the defendant to resist, and the effect the crime would produce upon the sexual organs. (*State v. Smith*, Phill. (N. C.), 302; *State v. Knapp*, 45 N. H., 148; *Woodin v. People*, 1 Park. Crim. Case (N. Y.), 464; *Cook v. State*, 24 N. J., 843. See also *Com. v. Lynes*, 142 Mass., 577, in a case of alleged incest.)

(4) As to whether an abortion has been performed or attempted. (*State v. Smith*, 32 Me., 370; *State v. Wood*, 53 N. H., 484; *Regina v. Still*, 30 U. C. (C. B.), 30; *Com. v. Browne*, 14 Gray (Mass.), 419.)

(5) As to the nature of a disease with which a person is or has been afflicted; its continuance; its severity and probable duration; the probability of its recurrence; its effect upon the general health; its cause; the remedy; its characteristics, whether hereditary; and as to the probable state of health of the person examined. (*Napier v. Ferguson*, 2 P. & B. (N. B.), 415; *Jones v. White*, 11 Humph. (Tenn.), 268; *Flynt v. Bodenhamer*, 80 N. Car., 205; *Polk v. State*, 36 Ark., 117; *Hook v. Stovel*, 26 Ga., 704; *Cock v. Potter*, 68 Pa. St., 342; *Linton v. Hurley*, 14 Gray (Mass.), 191; *Cooper v. State*, 23 Tex., 336; *Litch v. McDaniel*, 13 Ired. (N. Car.), 485; *Edington v. Ætna Life Ins. Co.*, 77 N. Y., 564; *Eckles v. Bates*, 26 Ala., 655; *Wiley v. Portsmouth*, 35 N. H., 303; *Filer v. N. Y. Central R. Co.*, 49 N. Y., 42; *Pidcock v. Porter*, 68 Pa. St., 344; *Anthony v. Smith*, 4 Bosw. (N. Y.), 503; *Matteson v. N. Y., etc., R. Co.*, 62 Barb. (N. Y.), 364; *Cooper v. State*, 23 Texas, 336; *Jones v. Tucker*, 41 N. H., 546; *Welch v. Brooke*, 10 Rich. (S. C.), 124; *Lake v. People*, 1 Parker's Crim. Cases, 495; *Pitts v. State*, 43 Miss., 472; *U. S. v. McGlue*, 1 Curtis (U. S.), 1; *Napier v. Ferguson*, 2 P. & B. (N. B.), 415; *Washington v. Cole*, 66 Ala., 212; *Janes v. White*, 11 Humph. (Tenn.), 268; *Moore v. State*, 17 Ohio, 521; *Morrissey v. Ingham*, 111 Mass. 63; *Sanderson v. Nashua*, 44 N. H., 492.)

f. Experts in the use of the microscope, the micrometer, or familiar with the scientific chemical tests, may give opinions as to whether blood is human, or that of animals, birds, or amphibia. (*Knoll v. State*, 55 Wis., 249; s. c. 42 A. M. Rep., 704; *Com. v. Sturtivant*, 117 Mass., 122; *State v. Knight*, 43 Me., 1.)

g. The confusion into which expert testimony in this respect has fallen in American courts is worthy of notice.

(1) Certain experts affirm that they can discriminate between human blood and that of all the domestic animals, save a dog, and from all mammalian blood, except the opossum, the guinea pig, the rabbit, the wolf, seal, beaver, monkey,

and a few others, by the diameters of the red blood corpuscles, under a microscope of very high powers. Others deny this, and assert that, while all mammalian blood can be distinguished from that of birds, fishes, and the amphibia by the shape of the red corpuscles and their structure, the extent to which the expert can go is to state that the blood is mammalian and is consistent with and similar to human or other mammalian blood. (R. U. Piper, in 15 Amer. Law Register, 561; 16 Amer. Law Register, 257; 19 Amer. Law Register, 529 and 593; 10 Central Law Journal, 183; 26 Amer. Law Register, 20; *Thomas v. State*, 67 Ga., 460; Reese, Text-Book Med. Jur., 2d Ed., 133; Wormley on Microchemistry of Poisons, 735-6; 1 Tidy Legal Medicine, Phila. Ed., 231; Prof. Richardson, in London Lancet, II, p. 210, 1875; I, pp. 321 and 700; Prof. M. D. Ewell, of Chicago, Micrometric Study of the Red Blood Corpuscles, Amer. Practitioner, of Chicago, 1890, pp. 79 and 173; Prof. H. F. Formad, of Phila., Studies of Mammalian Blood, Journal of Compar. Med. and Surgery, July, 1888; Clark Bell, Blood and Blood Stains, Med. Legal Journal, Vol. 10, No. 2.)

(2) A non-expert may testify that certain stains resembled blood. That is a fact that does not require skilled witnesses to see and recognize. (*Thomas v. State*, 67 Ga., 460; *McLain v. Com.*, 99 Pa. St., 86; *Dillard v. State*, 58 Miss., 368; *People v. Greenfield*, 30 N. Y. Sup. Ct., 462; s. c. 85 N. Y., 75; *People v. Gonzalez*, 35 N. Y., 49; *Rickerson v. State*, vol. 1, s. e., Rep. (Ga.), 178.)

*h.* Competent experts, after a chemical analysis, may give an opinion as to the presence of poison in the internal organs of the body.

(1) If a chemist or toxicologist, the witness need not be a physician or surgeon.

(2) A physician, if shown to be competent, may also so testify, and as to the symptoms of any particular person, and as to whether death resulted from the effects of any poison. (*State v. Bowman*, 78 N. Car., 500; 1 Crim. Law Mag., 294; *State v. Cook*, 17 Kan., 394; *State v. Terrell*, 12 Rich. (S. Car.), 321; *People v. Robinson*, 2 Park Crim. Cases (N. Y.), 236; *Polk v. State*, 36 Ark., 117; *Mitchell v. State*, 58 Ala., 448; *State v. Slagle*, 83 N. Car., 630; *Joe v. State*, 6 Fla., 591; *State v. Hinkle*, 6 Iowa, 380.)

*i.* A chemist may give his opinions concerning scientific facts or knowledge, upon scientific or technical facts, which his superior and scientific learning enables him to understand and elucidate, and which are beyond the reach of persons not skilled or informed in chemical science. Examples:

(1) Concerning the probability of the evaporation of spirits in certain casks. (*Turner v. The Black Warrior*, 1 McAllister (U. S.), 181.)

(2) Concerning the constituent parts of a mixture. (*Allen v. Hunter*, 6 McLean (U. S.), 303.)

(3) Concerning the safety of lamps. (*Bierce v. Stocking*, 11 Gray (Mass.), 174.)

(4) Concerning the nature of inks. (18 Am. Law Reg., 273; *Goodyear v. Vosburgh*, 63 Barb. (N. Y.), 154; *Clark v. Bruce*, 12 Hun (N. Y.), 271; *Sheldon v. Warner*, 45 Mich., 638; *Ellingwood v. Bragg*, 52 N. H., 448; *People v. Brotherton*, 47 Cal., 388.)

(5) Concerning noxious gases and their effect upon ground contiguous to a copper mill and the result of experiments therewith. (*Lincoln v. Taunton Mfg. Co.*, 9 Allen (Mass.), 182; *Salvin v. North Brancepeth Coal Co.*, L. R. Ch. App., 705.)

(6) Concerning the analysis of dirt drained by a filter basin, as to the practical utility of the drainage. (*Williams v. Taunton*, 125 Mass., 34.)

*j.* A competent farrier may testify as to whether a horse is sound or not, and a veterinary surgeon may give his opinion. (*Pierson v. Hoag*, 47 Barb. (N. Y.), 243; *Pinney v. Cahill*, 48 Mich., 584; *Spear v. Richardson*, 14 N. H., 428.)

(1) One not a farrier, if experienced with horses, is competent to say whether the eyes are good or bad, and give his opinion as to defects in the eyes. (*House v. Frost*, 4 Blackf. (Ind.), 293; *Slater v. Wilcox*, 57 Barb. (N. Y.), 604.)

(2) Anyone familiar with horses is competent to state whether a horse seemed well or sick. (*Spear v. Richardson*, 34 N. H., 428; *Willis v. Quimby*, 11 Fost (N. H.), 489.)

(3) A non-expert can not give an opinion as to the appearance and symptoms of cattle alleged to be starved to death. (*Stonan v. Waldo*, 17 Mo., 489.) Nor as to certain appearances in horses alleged to have been overdriven or exposed. (*Moulton v. Scruton*, 39 Me., 288.) Nor as to whether a certain wound is likely to be fatal. (*Harris v. Panama R. Co.*, 3 Bosw. (N. Y.), 7.)

*k. Insanity.*—(1) The opinions of expert alienists and of medical men who are shown to be competent, from knowledge, study, or experience in such cases, are admissible as to the sanity or insanity of a person at a given time; and this evidence can be based upon their personal knowledge and information, or in answer to hypothetical questions based upon the testimony disclosed. (*Conn. Mutual Life Ins. Co. v. Lathrop*, 111 U. S., 612; *Dexter v. Hall*, 15 Wall. (U. S.), 9; *Fairchild v. Bascomb*, 35 Vt., 398; *Tulis v. Kidd*, 12 Ala., 648; *Grant v. Thompson*, 4 Conn., 203; s. c., 10 Am. Dec., 119; *Rawble v. Tryson*, 7 S. & R. (Pa.), 90; s. c., 10 Am. Dec., 444; *State v. Feltes*, 51 Iowa, 495; *Dejarnette v. Commonwealth*, 75 Va., 867; *U. S. v. Guiteau*, 3 Crim. Law Mag., 347; *State v. Baber*, 74 Mo., 292; *People v. Hall*, 48 Mich., 482; *People v. Schuyler*, 106 N. Y., 298; *Quaife v. Chicago*, etc., R. Co., 48 Wis., 513; in the matter of the Will of Blakely, 48 Wis., 294; *Goodwin v. State*, 96 Ind., 550; *Coryell v. Stone*, 62 Ind., 307; *Davis v. State*, 35 Ind., 496; *Buswell on Insanity*, section 250; *Boardman v. Woodman*, 47 N. H., 120; *Commonwealth v. Rogers*, 7 Met. (Mass.), 500.)

(2) Non-professional witnesses who are not experts, who have known and been familiar with the person whose mental condition is in question, may state facts, conversations, and circumstances within their personal knowledge, and then give their opinions as to the sanity or insanity of the person. (*Cram v. Cram*, 33 Vt., 15; *Charter Oak Life Ins. Co. v. Rodel*, 95 U. S., 232; *Hardy v. Merril*, 56 N. Y., 227 (overruling the previous decision of the court upon the point); *Beaubien v. Cicatte*, 12 Mich., 459; *Grant v. Thompson*, 4 Conn., 203; *Clark v. The State*, 12 Ohio St., 483; *Clary v. Clary*, 2 Ired. (N. Car.), 78; *Baldwin v. State*, 12 Mo., 223; *State v. Erb*, 74 Mo., 199; *Walker v. Walker*, 14 Ga., 242; *Chace v. State*, 31 Ga., 424; *Wood v. The State*, 58 Miss., 741; *Webb v. State*, 5 Tex. App., 596 (overruling previous decisions in Texas); *Garrison v. Blanton*, 48 Tex., 299; *Norris v. State*, 16 Ala., 776; *Leach v. Prebster*, 39 Ind., 492; *Schlencker v. State*, 9 Neb., 241; *Kilgrove v. Cross*, 1 McCrary C. C., 144; *Pinney's Will*, 27 Minn., 280; *Conn. Mut. Life Ins. Co. v. Lathrop*, 111 U. S., 612; *O'Brien v. People*, 36 N. Y., 276; s. c., 48 Barb. (N. Y.), 274; s. c., 22 Amer. Rep., 441 (overruling); *State v. Pike*, 49 N. H., 399; s. c., 6 Am. Rep., 533; *Pidcock v. Potter*, 68 Pa. St., 342 s. c., 40 Am. Dec., 481; *Sutherland v. Hankins*, 56 Ind., 343; *Eggers v. Eggers*, 57 Ind. 461; *State v. Newlin*, 69 Ind., 108; *Doe v. Reagan*, 5 Blackf. (Ind.), 217; s. c. Am. Dec., 466; *State v. Hayden*, 51 Vt., 296; *Uptone v. People*, 109 Ill., 169; *Polin v. State*, 14 Neb., 540; *People v. Wreden*, 59 Cal., 392; *Coles v. State*, 75 Ind., 511; *Dejarnette v. Commonwealth*, 75 Va., 867; *Dunham's Appeal*, 27 Conn., 193; *Hathaway v. Ins. Co.*, 48 Vt., 335; *Morse v. Crawford*, 17 Vt., 499; *Potts v. House*, 6 Ga., 324; *Vanauken's Case*, 2 Stock. Ch. (N. J.), 190; *Brooke v. Townshend*, 7 Gill (Md.), 10; *Dewitt v. Barley*, 17 N. Y., 342; *Hewlett v. Wood*, 55 N. Y., 634; *Clapp v. Fullerton*, 34 N. Y., 190; *Rutherford v. Morris*, 77 Ill., 397; *Duffield v. Morris*, 2 Harr. (Del.), 375; *Wilkinson v. Pearson*, 23 Pa. St., 119; *Dove v. State*, 3 Heisk. (Tenn.), 348; *Butler v. Ins. Co.*, 45 Iowa, 93; *People v. Sanford*, 43 Cal., 29; *State v. Klinger*, 46 Mo., 229; *Holcombe v. State*, 41 Tex., 125; *McClaskley v. State*, 5 Tex. App., 320; *Norton v. Moore*, 3 Head (Tenn.), 482; *Powell v. State*, 25 Ala., 28.)

## V.

(6) *Exceptions to both rules.*—(1) The subscribing witnesses to a will may always give their opinions as to the sanity or insanity of the testator at the time he signed the will in their presence, whether they are experts or not, and without reference to who they are. The reason of this lies in the fact that the law provides that the proof of the will must rest upon their evidence, and in the nature of things their evidence is competent upon all questions necessary to be established to prove the will. And this does not depend upon whether they state the facts or circumstances upon which their opinion is based or not. (*Williams v. Lee*, 47 Md., 321; *Van Huss v. Rainbolt*, 42 Tenn., 139; *Hardy v. Merrill*, 56 N. H., 227; *Poole v. Richardson*, 3 Mass., 330; *Potts v. House*, 6 Ga., 324; *Dewitt v. Barley*, 9 N. Y., 371; *Grant v. Thompson*, 4 Conn., 203; *Wogan v. Small*, 11 S. & R. (Pa.), 141; *Robinson v. Adams*, 62 Me., 369; *Williams v. Lee*, 47 Md., 321; *Buswell on Insanity*, secs. 240, 265-266.)

(2) In some States the opinions of nonexpert witnesses as to the sanity or insanity of a person is not received, and have been excluded upon the ground that they are not proper exceptions to the general rule, which excludes the opinions of witnesses upon subjects concerning which they have no special or scientific knowledge.

Notably in Massachusetts, where the courts still adhere to this doctrine. (*Hastings v. Rider*, 99 Mass., 622; *Townsend v. Pepperell*, 99 Mass., 40; *Phelps v. Hartwell*, 1 Mass., 71; *Poole v. Richardson*, 3 Mass., 330; *Needham v. Ide*, 5 Pick. (Mass.), 510; *Commonwealth v. Wilson*, 1 Gray, 337; *Commonwealth v. Fairbanks*, 2 Allen (Mass.), 511; *Buswell on Insanity*, sec. 248; *Amer. and Eng. Encyclo. of Law*, vol. 7, p. 504; *Cowles v. Merchants*, 140 Mass., 377; *May v. Bradley*, 127 Mass., 414; *Commonwealth v. Brayman*, 136 Mass., 438; *Baxter v. Abbott*, 7 Gray (Mass.), 71.)

Also in Maine. (*Wyman v. Gould*, 47 Maine, 159; *Heald v. Thing*, 45 Me., 392; *Inhabitants of Fayette v. Inhabitants of Chesterville*, 77 Me., 28; s. c. 52 Am. Rep., 741.)

Also in Texas. (*Gehrke v. State*, 13 Texas, 508; *Hickman v. State*, 38 Texas, 191.)

And in Iowa and Mississippi. (*State v. Geddis*, 42 Iowa, 268; *Reed v. State*, 62 Miss., 405.)

In New York the early decisions were adverse to the admission of nonexpert evidence. (*Sears v. Shafer*, 1 Barb., 408; *Dewitt v. Barley*, 9 N. Y., 371; *Same v. Same*, 17 N. Y., 340; *People v. Lake*, 12 N. Y., 358; *Gardiner v. Gardiner*, 34 N. Y., 155; *Deshon v. Merchants' Bk.*, 8 Bosw. (N. Y.), 461; *Clapp v. Fullerton*, 34 N. Y., 190, 461; approved in *O'Brien v. People*, 36 N. Y., 276.)

But the doctrine has since been settled in that State that nonexperts may testify as stated in above subdivision *a*, in accordance with what may be regarded as now the well-settled general rule. (*Hewlett v. Wood*, 55 N. Y., 634; *Howell v. Taylor*, 11 Hun (N. Y.), 214; *Arnold's Will*, 14 Hun (N. Y.), 525; *Sisson v. Conger*, 1 T. & C. (N. Y.), 564; *Goodell v. Harrington*, 3 T. & C. (N. Y.), 315; *Real v. People*, 55 Barb. (N. Y.), 576; s. c. 42 N. Y., 270.)

(3) Courts have held that a Roman Catholic priest, who is required by his priestly office to pass upon the sanity or mental state of those who receive the sacraments at his hands, is a qualified expert, and as such may answer a hypothetical question as to the sanity of any individual. (*Estate of Toomes*, 54 Cal., 509; s. c. 35 Am. Rep., 83; *Amer. and Eng. Enc. of Law*, Vol. 7, p. 504.)

## VI.

(7) *Who is a competent expert in cases of insanity.*—To entitle a person to give an opinion as an expert the witness must be a person who is conversant with insanity, who has made the subject of mental diseases a special study, and, as stated in the rule defining what an expert is, he must be shown to have a particular and special scientific and technical knowledge upon the subject of insanity.

(Reese, Med. Juris. and Tox., 1891, p. 19; *Hastings v. Rider*, 99 Mass., 622; Buswell on Insanity, sec. 248, and cases there cited; *Commonwealth v. Rogers*, 7 Met. (Mass.), 500; s. c. 4 Am. Dec., 458; *Commonwealth v. Rich*, 14 Gray (Mass.), 355; *Clark v. Bruce*, 12 Hun (N. Y.), 271; *Kennedy v. People*, 39 N. Y., 245.)

*a.* An exception is made in case of the family physician, who is assumed to have superior knowledge and means of information more than ordinary persons, and who may give an opinion. (*Hastings v. Rider*, 99 Mass., 625; *Dickinson v. Barber*, 9 Mass., 225; s. c. 6 Am. Dec., 58; *Hathorne v. King*, 8 Mass., 371; s. c. 5 Am. Dec., 106.)

## VII.

(8) As all persons can testify from their knowledge, based upon facts under their own observation, as shown in subdivision *a*, *infra*, this embraces not only all physicians, but all experts, and leaves the question of opinion evidence by skilled experts narrowed to the true rule of opinion, testimony by skilled witnesses, and should be confined to hypothetical questions, a fact frequently lost sight of by courts and counsel.

*a.* Opinions of experts which usurp the functions or province of the jury are inadmissible, and should have little weight with courts or juries. For example, the question of insanity is a question of fact to be shown by evidence. The question of whether the accused is responsible is a question of law. The opinions of a medical expert, who by his opinion passes on the question of responsibility, usurps the functions of the jury, and such testimony lacks all the elements of evidence, and should have no weight. (Buswell on Insanity, secs. 253 and 254; *Princep v. Dyce Sombre*, 10 Mo. P. C., 232; *Stackhouse v. Horton*, 2 McCart, 202; *Watson v. Anderson*, 13 Ala., 202; *McAllister v. State*, 17 Ala., 434; *Slais v. Slais*, 9 Mo. App., 96; *Francke v. His Wife*, 29 L. Arm., 302; *Parnell v. Commonwealth*, 86 Penn. St., 260; *Regina v. Richards*, 1 F. & F., 87; *Fairchild v. Bascombe*, 35 Vt., 398; *The Province of Medical Expertism*, by Judge Charles G. Garrison, Med. Legal Journal, 1890, p. 486.)

*b.* It has been held "that the opinions of medical experts upon the subject of insanity are to be received with peculiar caution, for the reason that while an expert in the exact sciences, or in mechanics, has tangible or ascertainable facts on which to base his opinions, those scientists who profess to understand the quality or emotions of the human mind have in great part to rely upon mere conjectures for their inductions, which are often warped or fitted to pet theories or prejudices. The trend of judicial thought in America and England is that the mere opinions of medical experts are of little or no value in enlightening courts or juries as to the facts of the cases which are to be determined. (*People v. Lake*, 12 N. Y., 358; Buswell on Insanity, sec. 253; *Doughty v. Doughty*, 3 Halst. Ch., 643; *People v. Finley*, 38 Mich., 482; *Regina v. Southey*, 4 F. & F., 864.)

And in New York it has been held that where an expert witness has heard all the testimony and based his opinions upon it, he is not competent to give an opinion upon the general question of sanity or insanity, because his answer practically usurped the province of the jury, and that he should only be allowed to give an opinion as to what the facts proved or claimed to be proved indicated as to the mental condition of the party. (*People v. Lake*, 12 N. Y., 358; *People v. Thurston*, 2 Parker Cr. (N. Y.), 49; *Sanchez v. The People*, 22 N. Y., 147; *Arnold's Will*, 14 Hun (N. Y.), 525; *Hagadorn v. Conn. Mut. Life Ins. Co.*, 22 Hun (N. Y.), 249.)

## VIII.

(9) The dicta of the court in *Conn. Mut. Life Ins. Co. v. Lathrop*, 111 U. S., 612, in explaining the reason of the now almost universal rule allowing anyone, and especially nonexperts, to give an opinion based upon facts within their own personal knowledge, correctly states the law and the reasons of its general adoption.

Whether an individual is insane or not is not always best solved by abstruse metaphysical speculations expressed in the technical language of medical science. The common sense, and we may add the natural instincts, of mankind reject the supposition that only experts can approximate certainty upon such a subject. The truth is that the statement of a nonprofessional witness as to the sanity or insanity at a particular time of an individual whose appearance, manner, habits, and conduct come under his personal observation is not the expression of a mere opinion. In form it is opinion, because it expresses an inference or conclusion based upon observation of the appearance, manner, and motions of another person, of which a correct idea can not well be communicated in words to others, without embodying more or less the impressions or judgment of the witness. But in a substantial sense, and for every purpose essential to a safe conclusion, the mental condition of an individual as sane or insane is a fact. Not, indeed, a fact established by direct and positive proof, because in most, if not all, cases, it is impossible to determine, with absolute certainty, the precise mental condition of another. Yet, being founded on actual observation, and being consistent with common experience and the ordinary manifestations of the condition of the mind, it is knowledge so far as the human intellect can acquire knowledge upon such subjects.

a. As to the disposition, characteristics, or idiosyncrasies of a person any witness who knows is competent to testify and need not be an expert.

(1) As to whether he was fickle minded. (*Mills v. Winter*, 94 Ind., 329.)

(2) Whether he was intoxicated. (*City of Aurora v. Hillman*, 90 Ill., 66; *State v. Huxford*, 47 Iowa, 16; *Stacy v. Portland Put. Co.*, 68 Me., 279; *Pierce v. State*, 53 Ga., 365; *State v. Pike*, 49 N. H., 407.)

(3) Whether he was angry at a certain time. (*State v. Shelton*, 64 Iowa, 333.)

(4) Peculiar affection for a third person, if known to the witness or observed by him. (*McKee v. Nelson*, 4 Cow. (N. Y.), 355; s. c. 15 Am. Dec., 384.)

b. Masters of vessels or experienced seamen may give their opinions on questions pertaining to nautical science or affairs. (*Delaware & Co. v. Starrs*, 69 Pa. St., 36; *Baird v. Daily*, 63 N. Y., 547; *Western Ins. Co. v. Tobin*, 32 Ohio, 77; *Perkins v. Augusta Ins. Co.*, 10 Gray (Mass.), 312; *Parsons v. Mig.*, etc., Ore Co., 16 Gray (Mass.), 463; *Zugasti v. Lainer*, 12 Moore P. C., 331; *Reed v. Dick & Watts*, (Pa.), 479; *Jameson v. Drinkald*, 12 Moore, 148; *Fenwick v. Bell*, 1 C. & K., 312; *Carpenter v. Eastern Trans. Co.*, 71 N. Y., 574; *Dolz v. Morris*, 17 N. Y. Sup. Ct., 202; *Steamboat Clipper Co. v. Logan*, 18 Ohio, 375; *N. E. Glass Co. v. Lovel*, 7 Cushing (Mass.), 319; *Eastern Trans. v. Hope*, 95 U. S. 297; *Walsh v. Walsh*, etc., Ins. Co., 32 N. Y., 427; *Guiterman v. Liverpool*, etc., Ins. Co., 83 N. Y., 358; *Ogden v. Parsons*, 23 Howard (N. S.), 167; *Lapham v. Atlas Ins. Co.*, 24 Pick. (Mass.), 1; *Paddock v. Con. Ins. Co.*, 104 Mass., 521; *Moore v. Westervelt*, 7 Bosw. (N. Y.), 558; *Price v. Powell*, 3 N. Y., 322; *Leitch v. Al. Mut. Ins. Co.*, 66 N. Y., 100.)

c. Opinions may be given by persons skilled therein concerning the running and management of railway trains, and as to questions concerning railway construction, repairs, or management. [*Bellefontaine*, etc., R. Co. *v. Bailey*, 11 Ohio, 333; *Seaver v. Boston*, etc., R. Co., 14 Gray (Mass.), 466; *Cinn.*, etc., R. Co. *v. Smith*, 22 Ohio, 227; *Mobile*, etc., R. Co. *v. Blakely*, 59 Ala., 471; *Jeffersonville R. Co. v. Lanham*, 27 Ind., 171; *Hilton v. Mason*, 92 Ind., 157; *Fitts v. Creon City R. Co.*, 59 Wis., 323; *Baldwin v. Chic.*, etc., R. Co., 18 Am. Law Reg., 761; and note; s. c. 50 Iowa, 680.)

d. Generally an artisan, mechanic, or person skilled in any pursuit, avocation, or calling, may be examined as to matters relating to his avocation, concerning which he is shown to have peculiar and especial knowledge. (*Sheldon v. Booth*, 50 Iowa, 209; *Scattergood v. Wood*, 79 N. Y., 263; *Burns v. Welch*, 8 Yerg., (Tenn.), 117; *Inpitz v. People*, 34 Ill., 516; *Union Pacific R. Co. v. Clopper*, 102 (U. S.), 708; *Woodruff v. Imperial Fire Ins. Co.*, 83 N. Y., 133; *Ward v. Kilpatrick*, 85 N. Y., 413; *Campbell v. Russell*, 139 (Mass.), 278; *Terre Haute v. Hudnut*, 18 Am. and Eng. Corp. Cas., 302; *Folkes v. Chadd*, 3 Doug. (Mich.), 157; *Barnes v. Ingals*, 39 Ala., 193; *Davis v. Mason*, 4 Peck (Mass.), 156; *Knox v. Clark*, 123 Mass., 216; *Brantly v. Swift*, 24 Ala., 390; *Phelps v. Terry*, 3 Abb. Dec. (N. Y.), 607.)

e. Competent experts, qualified by study and experience, may testify as to the identity or genuineness of handwriting. (*Plunkett v. Bowman*, 2 McCord (S. Car.), 139; *Morrison v. Porter*, 35 Minn., 425; s. c. 59 Am. Rep., 331; *Moore v. United States*; 91 U. S., 270.)

f. Foreign laws can be proved by an expert shown to be competent, if unwritten. If written, a certified copy is the best evidence. (*Talbot v. Seeman*, 1 Cranch (U. S.), 1; *Drake v. Glover*, 30 Ala., 382; *Shed v. Augustine*, 14 Kansas, 282; *Church v. Hubbard*, 2 Cranch (U. S.), 187; *Dougherty v. Snyder*, 15 S. & R. (Pa.), 84; *Walker v. Forbes*, 31 Ala., 9; *Hoes v. Van Alstine*, 20 Ill., 202; *Barrows v. Downs*, 9 R. I., 446, 453; *Roberts's Will*, 8 Paige (N. Y.), 446.)

## IX.

(10) Opinions of witnesses are never received if all the facts can be otherwise ascertained and made intelligible to the jury, or if the question is one that men in general can understand and comprehend. (*Clark v. Fisher*, 1 Paige (N. Y.), 171; s. c. 19 Amer. Dec., 402; *Stowe v. Bishop*, 58 Vt., 498; *Penn Co. v. Conlan*, 101 Ill., 93; *Passmore's Appeal*, 27 N. W. Rep., 601; *Hallahan v. N. Y., etc., R Co.*, 102 N. Y., 104.)

a. Concerning the ordinary affairs of life the jury can form intelligent opinions, and opinions of experts are inadmissible. (*Bemis v. Centr. Vt. R. Co.*, 58 Vt., 636; *Milwaukee, etc., R. Co. v. Kellogg*, 94 U. S., 469; *Schneider v. Barney*, 113 U. S., 645; *Durrell v. Bederly*, 1 Holt, 285; *Campbell v. Richards*, 5 B. & Ad., 846; *Carter v. Boehm*, 3 Burr, 1905; *Higgins v. Dewey*, 107 Mass., 494; *Neilson v. Chic., etc., R. Co.*, 59 Wis., 516; s. c. *Watson v. Milwaukee, etc., R. Co.*, 57 Wis., 332; *Gilbert v. Guild*, 144 Mass., 361; *Knole v. State*, 55 Wis., 249; s. c. 42 Am. Rep., 704.)

## X.

(11) The competency of an expert is a question for the court, and it must be clearly shown before his testimony can be received as an expert. (*Stennett v. Pa. Ins. Co.*, 68 Iowa, 674; *Russell v. Crittenden*, 53 Conn., 564; *Ft. Wayne v. Coombes*, 107 Ind., 75; *Higbee v. Guardian Ins. Co.*, 53 N. Y., 603; *Russell v. Crittenden*, 53 Conn., 564; *Hinds v. Harbon*, 58 Ind., 121; *McEwen v. Bigelow*, 40 Mich., 215; *Dole v. Johnson*, 50 N. H., 452; *Castner v. Sliker*, 33 N. J. L., 96; *Flint v. Bodenheimer*, 80 N. Car., 205; *Perkins v. Stickney*, 132 Mass., 217; *Wright v. Williams's Estate*, 47 Vt., 222.)

## XI.

(12) *Hypothetical questions.*—The rule is that a party is entitled to put his case hypothetically, as he claims it to have been proved, and take the opinion of the witnesses thereon, leaving the jury to determine whether the question put covers the case as proved. (*Bishop v. Spining*, 38 Ind., 143; *Guetig v. State*, 66 Ind., 94; *Goodwin v. State*, 96 Ind., 550; *Cowley v. People*, 83 N. Y., 464; s. c. 38 Am. Rep., 464; *Quinn v. Higgins*, 63 Wis., 664; s. c. 53 Am. Rep., 305; *Page v. State*, 61 Ala., 16; *Boardman v. Woodman*, 47 N. H., 120; *Yardley v. Cuthbertson*, 108 Pa. St., 395; s. c. 56 Amer. Rep., 218; *Dexter v. Hall*, 15 Wall. (U. S.), 9; *Commonwealth v. Rogers* 7 Met. (Mass.), 500; s. c. 41 Amer. Dec., 458; *Forsyth v. Doolittle*, 120 U. S., 73; *State v. Cross*, 68 Iowa, 180; *Morrill v. Tegarden*, 19 Neb., 534; *Ray v. Ray*, 98 N. Car., 536; *People v. Augsburgh*, 97 N. Y., 501.)

a. The court should allow counsel great latitude in framing a question based upon the facts as claimed to be proved, if evidence tending to show the facts as claimed to be proved has been given; but the court should not allow hypothetical questions based on alleged facts which have not been proved, or not within the range of legitimate evidence, or containing inferences or conclusions, or when they ask for conjectures; nor those omitting material facts that are conclusively

shown. (*Goodwin v. State*, 90 Ind., 550, disapproving *People v. Thurston*, 2d Park. Crim. Cases (N. Y.), 49; *Strong v. Stevens Point*, 62 Wis., 255; *Haisle v. Payson*, 107 Ill., 365; *Cowley v. People*, 83 N. Y., 464, and cases there cited; *Higbie v. Guardian, etc., Co.*, 53 N. Y., 603; *State v. Stanley*, 34 Minn., 430.)

## XII.

(13) It is the peculiar province of the jury to decide what weight, if any, they will give to the opinion of an expert. They are not bound by it, and may exercise their own experience upon the subject as to what weight it is entitled to receive. The court has no power over it, and where judges have instructed juries to give greater weight to the evidence of professional witnesses than to non-expert evidence, the verdicts have been set aside as illegal. (*Congress, etc., Co. v. Edgar*, 90 U. S., 645; *Schwenger v. Raymond*, 105 N. Y., 648; *Guetig v. State*, 64 Ind., 94; *State v. Bailey*, 4 La. Ann., 376; *Von Valkenburgh v. Von Valkenburgh*, 90 Ind., 433; *Stone v. Chicago, etc., R. Co.*, 33 N. W. Rep. (Mich.), 24; *Head v. Hargrave*, 105 U. S., 45; *Atchison, etc., v. Thul*, 32 Kan., 255; *Davis v. State*, 35 Ind., 496; *McGregor v. Armill*, 2 Iowa, 30; *Tolum v. Mohr*, 21 Ark., 349; *Chandler v. Barrett*, 21 La. Ann., 58; *Sanders v. State*, 94 Ind., 147; *People v. Montgomery*, 13 Abb. Pr. (N. S.), (N. Y.), 207; *Cunee v. Bessorné*, 63 Ind., 524; *State v. Cole*, 63 Iowa, 695; *Epps v. State*, 102 Ind., 539; *United States v. Molloy*, 31 Fed. Rep., 19; *Templeton v. People*, 10 Hun (N. Y.), 357; *Eggers v. Eggers*, 57 Ind., 461; *Goodwin v. State*, 96 Ind., 550; *Humphries v. Johnson*, 20 Ind., 190; *Spenaley v. Lancashire Ins. Co.*, 62 Wis., 443.

## XIII.

(14) An expert witness can not be compelled to give his opinion as an expert, unless he is compensated. He can not be punished for contempt in refusing to appear or testify as such without he is compensated, but he can be compelled to appear and testify to facts within his knowledge, the same as any other witness, without compensation above the statutory fee to which any witness is entitled. (*Buchanan v. State*, 59 Ind., 1; s. c. 26 Am. Rep., 75; 17 Alb. Law J., 242; *Dillis v. State*, 59 Ind., 15; *Webb v. Page*, 1 E. & K., 23; *Parkinson v. Atkinson*, 31 L. J. (N. S.), C. P., 199; *In re Roelker Sprague*, 276; *People v. Montgomery*, 13 Abb. Pr. (N. S.), 207; *United States v. Howe*, 12 Cent., L. J., 193.)

The courts of Alabama and Texas have held that experts are not entitled to extra compensation. (*Ex parte Dement*, 53 Ala., 389; *Sumner v. State*, 5 Tex. App., 365.)

But the weight of authority is otherwise. This subject has been exhaustively treated by Lawson in his work on Expert and Opinion Evidence, and by Rogers on Expert Evidence. The medico-legal authors all treat it, but in a general way. (*Wharton & Stillé*, 1882; *Dean*, 1873; *Elwell*, 1881, 1887; *McClellan*, 1872; *Ordronaux*, 1869, 1878; *Medico-Legal Papers*, series 1, 2, and 3, N. Y.; *Taylor*, all English and Phil. editions; *Woodman & Tidy*, 1876, 1884; *Naquet's Legal Chemistry*, 1876; *Taylor on Poisons*, 1875; *Field's Medico-Legal Guide*, 1882; *Reese, Med. Jur. & Tox.*, 1884, 1889, 1891; *Bucknill & Tuke*, all editions.)

The law authors on evidence (*Wharton*, *Starkie*, *Greenleaf*, *Taylor*, *Best*, *Wood*) all treat the subject in their works on evidence, to which the student and the expert should refer; *vide* also Prof. Washburn's paper in 1 Am. Law Review, 62.

For reference to authorities and decisions, the American and English Encyclopædia of Law and Abbott's New Digest are the best sources of information,

## ADDRESS OF THE PRESIDENT OF THE SECTION, DR. J. COLLINS WARREN, BOSTON, MASS.

## MEDICAL EDUCATION IN THE UNITED STATES.

GENTLEMEN: The work of this section is of a character which does not usually form a prominent part in the proceedings of medical gatherings. In almost every department of education pedagogy, or the science of teaching, is a recognized specialty. The rapid progress which has been made in medical education in this country within the last few years has brought about such profound changes in the methods of instruction and the strides which medical science is making all over the civilized globe are bringing into view so many new fields of work that the teachers of to-day have a far more complex and difficult task than was presented to their predecessors. The art of teaching medicine has never been taught, in this country, at least. The time has arrived to take up the subject. In introducing such a subject as this it seems appropriate to take a brief retrospective glance at the history of medical education in this country. There lies before me as I write a quaint little volume entitled *A Discourse upon the Institution of Medical Schools in America*, published in 1765. It bears the following inscription: "To Dr. John Warren, physician in Boston, this copy \* \* \* is presented by his respectful and affectionate friend, John Morgan, Philadelphia, February 27, 1783." This book may be safely regarded as the first contribution to the subject which we are to discuss to-day, and the two dates are memorable; the former indicates the foundation of the medical department of the University of Pennsylvania and the latter the birth of the medical department of Harvard University. Dr. Morgan justly remarks that "medicine is a science as important in its object as it is difficult in its acquisition. It is very extensive in its researches and presupposes the knowledge of many other sciences. The cultivation of it requires no small ability and demands of those who engage in the arduous pursuit an enlarged and benevolent mind." It is interesting to note that one whom we might justly look upon as the father of medical education in this country, and who "had spent five years in Europe under the most celebrated masters in every branch of medicine," should have taken so optimistic a view of the knowledge of medicine at that time as to say, "The industry of many centuries has already been employed to bring physic to that degree of perfection at which it is now arrived." Fortunately, he adds: "It will still require a long time to remove the obscurities which yet veil many parts of it." Three years after this book was written Pennsylvania held her first medical commencement and the provost justly remarked, "This may be considered the birthday of medical honors in America." The men who started this movement had received much encouragement from across the ocean, and the remark of one of their teachers, Dr. John Fothergill, of London, is of special interest to those concerned in the work of this congress. Writing to James Pemberton, in 1762, he recommends Drs. Shippen and Morgan as men well qualified for the work of teaching, "both of whom," he says, "will not only be useful to the province in their employment, but if suitably countenanced by the legislature will be able to erect a school of physic amongst you that may draw students from various parts of America and the West Indies." During the colonial period of our history it was the custom for young men who entered upon the study of medicine to become regularly apprenticed to some practitioner for a term of three or four years, during which time the preceptor was entitled to the student's services in preparing and dispensing medicines and services as an assistant in minor surgical operations. As a return for this the physician was obliged to give the student detailed and thorough instruction in all the branches of medicine. Many of the leading men frequently had several students in their offices,

constituting a small class, who were drilled as regularly in their studies as they would be in college. In some instances the term of apprenticeship was extended even to six and seven years.<sup>1</sup>

When the medical school sprang into existence it was at first intended merely to supplement the apprentice system, and as means of communication of one part of the country with another were exceedingly limited, it was found desirable to concentrate school work into as small a part of the year as possible. Hence the origin of the short term of four months which has clung so persistently to the American system. I will not undertake to weary you with a detailed account of the history of the development of our system of education. Suffice it to say that the close of the century found schools established not only in Pennsylvania and Massachusetts, but in New York, Maryland, and Vermont. There were, however, in 1810, only two medical schools in existence, with an aggregate number of medical students of about 650, of whom 100 received the degree either of bachelor or doctor of medicine. The bachelors' degree was given to those who had attended the full course of college instruction. It was hoped that such students, after a short period of practice, would eventually return to take the higher degree, but as this expectation was not fulfilled, the degree of bachelor of medicine was soon wisely abolished. A noticeable feature of the education of that early period in our medical history was the requirement for a high standard of general education. Those students who did not possess a college degree were expected to pass an examination in Latin, mathematics, and natural and experimental philosophy. To obtain the degree of doctor of medicine it was necessary that the applicant should have been a bachelor of medicine for at least three years, should have attained the age of 24 years, and should write and defend a thesis publicly in the college.<sup>2</sup> When we consider how imperfect was the knowledge of chemistry, physiology, and even anatomy, and many other branches of medical science, and how little of what we now consider the foundation of medical education there was to teach, such a course must be regarded as a very complete and exacting one. "Under these influences the first thirty years sufficed to cause the bachelor's degree to be abandoned by all the schools, the number of professors in each school to be doubled, and the length of the annual college term to be shortened one-third." (Davis.) Such was the standard of education with which the present century opened. New schools continued to be created, not infrequently in connection with some university, as in 1810 at Yale University, in 1817 in Lexington, Ky., in 1820 at Brunswick, Me., in 1825 at Charlottesville, Va., until in 1840 twenty-six new medical colleges had been added to the list—the whole number of students in the country amounting to 2,500, the population in that year being 17,069,453. A glance at the report of a committee to the Medical Society of the State of New York in 1833 gives a good idea of the amount of work done by the schools at that period. In the twenty schools mentioned in this report the number of courses of lectures required was two, with one exception, that of the University of Virginia, where three courses were required; and, to the credit of this university be it said, the length of each course was ten months, whereas the almost invariable custom of the other schools was to give a course of four months' duration only. The time of study purported, however, to be in all cases three years, "including the time devoted to lectures," as is stated in most of the reports. This straw indicates that at that time the chief dependence, or nearly so, was placed upon the extra-mural instruction which was given to the student. At Yale University there was this additional requirement, namely, that the student was required to study four years "if he had not graduated," which phrase, I presume, means if he had not already taken the academic degree. This seems to be the first intimation that a longer term than the

<sup>1</sup> N. S. Davis, *Med. Ed. and Med. Institutions in the United States of America*, 1877.

<sup>2</sup> William Pepper, *Higher Medical Education*, 1877.

standard then set was necessary for a complete equipment for the practice of medicine.

The Medical Institution of the State of Georgia (incorporated in 1828) gave at first the bachelor's degree with one year of study, but immediately abandoned it for the usual curriculum. In the University of Pennsylvania, to which we look for the standard in these early as well as later days, two full courses were required, but, as in many other schools, one course only was demanded from those who had attended a course at some other reputable school. In addition, a course of clinical instruction in one of the Philadelphia hospitals was required. The course was then for three years, but as the course of lectures was only four months, it was expected that during the remaining portion of the first two years the student should receive private instruction. As the period of the school term was so short, it is interesting to note at what time of the year the various courses of lectures began. This, it will be seen, varied greatly according to the geographical position of the institution. At Dartmouth and the University of Vermont the term began in August; in Bowdoin College, Maine, however, it began in the middle of February, continuing until the middle of May; that is, term time in the far North was in the summer or spring; at Yale and Harvard, and in Philadelphia and New York, the term opened at the end of October or the beginning of November, as did also the schools in South Carolina and Kentucky. The University of Virginia, with its long course of ten months, began September 10. Although the term time was exceedingly short in some schools, a large amount of work was crowded into the daily routine of the students. Five or six systematic lectures a day, with attendance on clinics and dissections when possible, was considered nothing more than a fair amount of work for the medical student to digest properly. This system of teaching continued practically unaltered in 1851, if we may judge from a report to the committee on medical education of the American Medical Association.<sup>1</sup> In regard to the private instruction which was supposed to continue during the remaining eight months of the year, the report states that a very large proportion of students simply read medicine under the direction of their preceptors. Anything like careful instruction upon the part of the teachers did not exist. The student, neither while attending lectures nor while in his preceptor's office, was encouraged in anything like faithful and rigid study. To remedy this defect private schools for teaching medicine were founded by enterprising physicians and surgeons, and these quiz classes which were here inaugurated became a prominent feature of the national system of teaching. Many a distinguished professor has won his spurs in these private schools, and many valuable experiments in medical education carried on by these men. As the college term has lengthened the necessity for these accessory courses has diminished, and in many cities the extra course instruction, whether by private school or teacher, has passed into history. No one will, I presume, regret the departure of the year of private teaching "by some respectable practitioner" whose certificate, purchased by a handsome fee, came eventually to have so little meaning. When this custom was first inaugurated it was the sole method of instruction, and during the long period of apprenticeship the student received a large amount of instruction of the most valuable sort. When the medical school came into existence the attempt was made to combine the two systems. The practitioner, relieved from the responsibility of giving a complete course of study to the student, gradually relaxed his efforts as a teacher until this part of his daily work came to have only a nominal value. According to Davis it consisted in 1877 in little more than the registry of the student's name in the doctor's office, permission to read the books of his library, or not, as he chose, and the giving of a certificate of time of study for the student to take to the medical college where

---

<sup>1</sup> W. Horker, M. D., 1851.

he expected to graduate. At the beginning of this century the successful practitioner gave a prominent place in his household to the medical student. I have often heard my father, and many other practitioners of his day, tell stories of the school life of those times. The office in the old homestead where I began the practice of medicine, then a luxurious library, was in those times a plain room with a sanded floor, occupied during the day by a small band of medical students who all boarded in the same house. The old room was the scene of many amusing stories of schoolboy life, and also of thrilling tales of escape from the indignant pursuer of the hero of some graveyard scrape, which was rendered necessary by the peculiar laws of that period. This phase of student life has long since passed away, and the equally agreeable and far more profitable experience of hospital life has taken its place. Would that I could add that such experience was now the privilege of every medical student in the land.

As we approach the middle of the century we find the nation growing rapidly in population and prosperity, and a corresponding increase in the numbers and activity of the medical profession. From 1830 to 1845 the number of medical schools in the United States had more than doubled. At a meeting of the Medical Society of the State of New York in 1839, when the subject of medical education was brought forward, it was proposed to hold a national medical convention the following year in Philadelphia, consisting of representatives from the different schools and State societies. No response was made to the action of this society; but in 1844 Dr. N. S. Davis, then a delegate from Broome County, N. Y., offered a resolution that a national convention be called in 1846, and the American Medical Association thus sprang into existence, the fundamental idea which brought about the formation of the association being the improvement of our system of medical education. It was high time that some such movement should take place, as the rapid increase in the number of medical schools brought with it a constant increase in the laxity of methods of teaching. The equipment of a new school was sometimes pathetic in its meagerness, a manikin and a few lecture rooms often constituting the entire "plant" of the infant institution. It would not do to question the dean too curiously about the clinical facilities which the school enjoyed, and as for laboratory work, there were few teachers sufficiently advanced in their ideas to think of criticising the absence of such instruction. There was, indeed, no time for it. Every available space in the tabular view was filled with lecture hours. Professors were asked to come from neighboring towns to assist in teaching, and often gave two lectures in the same day. This cramming process, which seems so thoroughly American in its hustling activity, is perpetuated to the present day in a limited number of schools, chiefly those situated far from medical centers. As Holmes has said, life at that time was cheap—medical visits in the country were only worth 25 cents apiece—and the ambitious student could not afford to make an expensive outlay for his future work. The American Medical Association thereupon justly put on record its opinion "that the abuses which exist in the modes of medical education pursued in this country demand the serious consideration of the profession," and at each meeting it continued to sound a note of warning on this all-important subject. One of the principal reforms which it proposed to bring about was the lengthening of the term of each year from four to six months, and you will doubtless be somewhat surprised to hear that at the second meeting of the association, which was held in Boston, a paper was presented from the faculty of Harvard University opposing this proposition. *Tempora mutantur, et nos mutamur in illis.* If Harvard was unwilling to lead in the matter of reform at that time, it is not surprising that the other schools should not have been persuaded to change their customs. To the Chicago Medical College, which was founded in 1859, must be given the credit of having been the first to attempt to lengthen the college course and to establish

the system of teaching upon the so-called "graded plan."<sup>1</sup> The school was in fact organized for this express purpose. Little change was, however, effected by the association in the methods of teaching at that time, although the discussions which were constantly held were destined eventually to bring forth good fruit. During the following decade little was done in the way of reform.

Graduating from the academic department of Harvard in 1863, I had an opportunity to study personally the methods in vogue at that time, and am the more competent to express an opinion, as I passed one year of my course of study in Philadelphia. The old system of medical education was then in all its glory, and presented a striking contrast to one who had been subjected for four years to the strict discipline of a well-conducted university. The course of lectures in Philadelphia began about the 1st of November. The day was occupied in a bewildering succession of lectures, on all of which the student felt called upon to attend, as he had been obliged to "take out tickets" for the full course. The teachers were able, conscientious, and in many cases brilliant men, and many a lesson there learned has been of value in after life. Clinical teaching was, however, largely crowded aside by the superabundance of systematic lectures. The course came to an end on the 1st of March, and the class, which was an enormous one, was allowed to scatter to the four quarters of the country. Many of my classmates returned the following autumn, and after attendance on a second course of lectures, and having also handed in the certificate of study from the "respectable practitioners," were able to graduate in the following March; that is, after having been connected with the school less than eighteen months. This may appear to the younger members of this section an absurdly short "curriculum," but there were a considerable number of enterprising young men who did not propose to occupy a long time in obtaining their education.

You will remember what has already been said about the period of the year occupied by the school term. At that time there were not only schools who had their college "year" in the winter, but there were spring "years" and summer "years" as well. Several of my friends proposed accordingly, after leaving Philadelphia in March, to take a spring "year" at another school, in accordance with a custom which many at that time followed. Such a student was therefore able, on July 1, to show to the examining body tickets for two full courses of lectures and a letter testifying to private instruction. It was notorious that many students at that time were able to obtain a degree after nine months only of medical study. The custom of short courses of study at different periods of the year unfortunately still prevails. This zodiacal paradox has not yet been fully eliminated from the medical calendar. The condition of teaching at Harvard was practically the same as at Philadelphia. It is not surprising that the best class of students were dissatisfied with the opportunities and that the number of them who found it necessary to go to Europe to complete their education was constantly increasing. Two and even three years of study was not considered too long a time to occupy in this manner. It is true that spring terms of a supplementary nature were organized by most schools and those students who chose to remain could receive instruction throughout the year. The majority of students, however, disappeared, many of them employing their time in other occupations to earn sufficient money to pay for a second course of lectures. The class of individuals who studied medicine at that time seemed far inferior to the medical students of to-day in culture and refinement. President Eliot says of the students of that period: "In this university until the re-formation of the school in 1870-'71 the medical students were noticeably inferior in bearing, manners, and discipline to the students of the other departments; they are now (1888) indistinguishable from other students." The date which I have just mentioned marks the era of a great change in the history

---

<sup>1</sup> N. S. Davis's Contributions to the History of Med. Ed., etc., 1877.

of medical education. The rising generation of teachers were not content with the antiquated methods of a previous century; they had learned of a new order of things in the centers of medical learning in Europe, and as the old generation of teachers went out and a new one came in the modern ways of teaching grew into a substantial system which had come to stay. Harvard adopted the graded course of three years' study, but she also did far more than that—and in this respect she stands in advance of almost every other school in the country. She lengthened her course to nine months, so that her two terms correspond with those of the other departments of the university and represent a full year's work. I will not undertake to record the history of the reform in medical education since that time; it is familiar to most of you. The example which has been set to the rest of the country by the University of Pennsylvania and by the College of Physicians and Surgeons of New York are too well known for me to repeat them here.

While criticising, as I have done, the work of a previous generation, I ought to remind you that our forefathers accomplished what they did only by individual efforts. There were no Government endowments, and, as a rule, no liberal benefactors to back them in their undertakings. Their schools had to be conducted on business principles, with a keen eye to the financial success of their venture. During the past twenty years, it is true, a number of State universities have been established. In the University of Michigan, and possibly in one or two other State universities, the medical professorships, like those of other departments, are sustained by the income from the general endowment, independent of fees derived from medical students, but, as a rule, the success of the school has depended upon the patronage which it has received. It may be justly said, therefore, that the whole system of medical education in this country is the spontaneous outgrowth of the work of the medical profession, and that it is due to their public spirit and disinterestedness that so important a department in the educational development of a great nation has been brought to its present state of excellence. The good work has, however, but just begun. The reform of medical education is still in its infancy. If we are to believe all the glowing announcements which we read in the annual catalogues of the various schools, we might be lulled into a sense of calm security for the future, but, unfortunately, the actual practice of many, I might say a majority, of the schools does not come up to the ideals which are here set forth.

The essential points in the new scheme of education have been well stated by our president, Dr. Pepper.<sup>1</sup> (1) The establishment of a preparatory examination. (2) The lengthening of the period of study to at least three full years. (3) The careful grading of courses. (4) The introduction of ample clinical and laboratory instruction. (5) The establishment of fixed salaries for the teachers.

In a general way we may obtain some notion of the improvement which has been made by a study of the report of the Illinois State Board of Health for 1891. According to this report there are now 148 medical schools of all kinds in the United States and Canada. The number of these requiring certain educational qualifications for matriculation is 129. The number of schools requiring attendance on three or more courses of lectures was, in 1882, 22; in 1891 the number was 85. There has been also a gradual increase in the duration of the lecture terms from an average of 23.5 weeks in 1882-'83 to 26.3 weeks in 1890-'91. In 1882-'83 there were 8 colleges that had but sixteen weeks. The number of colleges having terms of six months or more is now 111. The number of colleges which have graduated students at the end of the second course of lectures the present year is less than 10 per cent of the whole number of schools in the country. There are now in the United States 32 examining and licensing bodies that do not give

---

<sup>1</sup> Introductory address, Philadelphia, 1877

instruction. Although the work of these licensing boards is far from uniform, a great deal has been accomplished by them. There are at the present time fifteen States with practice acts that require an examination of all persons desiring to practice medicine in the respective Commonwealths. These States include nearly 50 per cent. of the entire population. In many States the whole complexion of the medical practice has been changed by the clarifying influences of these bodies. The reports on medical education by the Illinois board, I do not hesitate to say, have exerted a more powerful influence on the movement in education than any other publication which our medical literature has produced. The effects of these medical-practice acts, which establish a minimum of time spent at medical lectures and provide an examination for those who wish to become practitioners, are shown in the statistics which have just been given. At the present time State examinations are required in Minnesota, North Dakota, Montana, Washington, North Carolina, Alabama, Florida, Virginia, New Jersey, New York, Nebraska, Maryland, and Utah. Millard,<sup>1</sup> who has had experience in framing the act of Minnesota, believing that it would be an improvement upon the medical-practice acts at present in existence to separate the two functions of the board, the licensing power and the educational supervision, thinks that the best interests of the public will be subserved by assigning the duties of the State licensing power to the various State boards of health. The regulation of all forms of education should, on the other hand, be vested in a central power consisting of a single board, to be known as a State bureau of education, with power to regulate all educational institutions granting degrees, together with the power of granting charters and revoking the same. Particularly should this apply to all institutions wishing to afford the community any of the various forms of higher or special education.

Having thus sketched the progress of medical education up to the present time, let us now glance at some of the points of the present system in which it is desirable that further improvement should be made. The importance of a preliminary training for the study of medicine is a problem which has occupied the attention of our most prominent teachers. That the medical student should have received a fair amount of education goes without saying. The importance of a proper preliminary education is thus forcibly stated by that most experienced of German medical teachers, Prof. Billroth. He says in reply to the objection to a preliminary study of the natural sciences as a basis of a medical education:

The educated of all nations should not fail to encourage to their utmost knowledge and study in all countries and stations of life. They should not fail to maintain and increase gradually the standard which they have set up both for themselves and others. They should not fail to support the Government in all efforts directed toward this end. The physician, the lawyer, the school-teacher, and the clergyman form the true nucleus of culture in the community. They are, especially in the country and small towns, the representatives of the educated elements of society. The people seek their advice in time of need, and they are their sole source of knowledge in many things. To neglect the education of such persons, to lower their mental and scientific standard, to bring them up so that they have no better education than the tradesman, the tailor, and the cobbler, would be, in my opinion, the suppression of the educational development of a nation, and is a policy both corrupting and immoral in principle, as it would inevitably ruin a nation and bring it prematurely to that point of decadence when it would become the prey of others.

The importance of these views is fully appreciated in Germany, where the professional schools are integral parts of the university, and entrance to the professional schools depends upon the previous completion of the course in philosophy, a course which corresponds to that of our academic degree. In Dr. Holmes's suggestive article on this subject<sup>2</sup> it is shown that while the increase in the total num-

<sup>1</sup>Millard. The Necessity and Best Methods of Regulating the Practice of Medicine. *Journal Amer. Med. Assoc.*, July 30, 1892.

<sup>2</sup>The forthcoming report of the Bureau of Education on professional education in the United States, *Journal American Medical Association*, January 14, 1893.

ber of medical students has been very great during the last decade, the increase in the number of college men who have entered the profession has been very slight, and in some of the more prominent schools the percentage has even slightly diminished. He says:

It can not, then, be doubted that relatively a smaller number of medical students have a bachelor's degree than in 1880, though the education of the average medical student is superior to the average medical student ten years ago.

Although the proportion of medical students to students of law and divinity is greater in the United States, the relative proportion has diminished in the last ten years, whereas in Germany in the same period; a period during which medicine has become more of a science and the domain of surgery has increased under anti-septic methods, the proportion of medical students to the students of other professions has greatly increased. The reason for this variation in the proportion of medical students in the two countries is explained by the imperfection of our system of education. Educators have not had proper control, and medicine has not been placed upon that dignified scientific basis which it enjoys in Germany. Dr. Holmes complains that the medical department is neglected by every university in the United States. "It is farmed out or left to shift for itself."

Harvard has recently made an attempt to overcome this difficulty by a modification of the academic course, as Welch points out in an article on this subject.<sup>1</sup> If a young man choose the medical profession he should devote at least four years to medical studies, including the preliminary sciences. If he supplements this with a year in a hospital and a year or two in study abroad, and all this work has been preceded by a college academic course, he would not be able to enter upon the practice of his profession much before the age of 30. Dr. H. P. Bowditch,<sup>2</sup> dean of the medical faculty of Harvard, has strongly advocated a change which would overcome this difficulty. The average age of students who enter the Harvard academic department, as President Eliot has shown, has been gradually rising during the whole of this century until it has reached nearly 19 years. The student who enters the medical school therefore finds himself just beginning the preparation of the real work of his life at an age when many of his contemporaries are already engaged in the productive work of their professions. In Germany the best class of students begin their professional studies at a little earlier age than that at which our young men enter Harvard College. As the course of study leading to the degree of doctor of medicine lasts five years, it follows that the German physician is ready to begin practice before he is 23½ years old. The average age of matriculants at Oxford is 19 years, and it is perfectly possible for an Oxford student desiring to study medicine to begin his purely professional studies before the end of his second year of college life. The dean writes me upon this subject as follows:

There are many students in our school who have had one or two years of college life, either as special or regular students, and then have entered the medical school because they have felt the necessity of getting started on their life work. These men would have been glad to take the bachelor of arts degree if it could have been procured in a shorter time, but they consider it too dearly purchased when it involves so much delay in beginning their professional life.

It seemed, therefore, reasonable to the medical faculty of Harvard to make the following proposition, namely: That the academic council should consider the expediency of granting the degree of bachelor of arts to all undergraduates who should subsequently take the longest course of study offered at the professional schools after three years' attendance in the academic department, the professional degree and that of bachelor of arts to be given simultaneously at the end of the

<sup>1</sup> Some of the Advantages of the Union of Medical School and University, 1888.

<sup>2</sup> Remarks Made at a Meeting of the Academic Council, 1887.

professional course. One of the medical studies at least can be obtained in the usual college curriculum, and general chemistry is frequently "anticipated" by students who enter the medical school. It is hoped, indeed, that this course will soon become one of the "preliminary studies" to medicine. It would be a short step to place one or two more of the scientific medical studies on the list of academic elections, and a whole year could thus be anticipated. The relations of professional schools to the university are not appreciated in the same light that they are in Germany, and the proposition of the medical faculty, after much discussion, was finally declined. The advantages of a more intimate relation between the medical school and the university are clearly set forth by Welch in the article referred to. The duplication of laboratories is thus avoided, and men in different branches of science are brought more intimately together. The important departments of botany, zoölogy, and comparative anatomy can not fail to have an elevating influence upon the work done in a medical school. How much more rapidly might not original investigation progress when different branches of science work in a common cause. It is here that the great strength of German science and progress takes its origin. A movement in the same direction is the establishment in our colleges and scientific schools of courses of tuition intended specially for the benefit of those who intend ultimately to study medicine. Such a course has been planned by Prof. Shaler in the Scientific School of Harvard, and a similar course is offered by the Institute of Technology. Prof. Shaler's course preparatory to medicine consists of two years. In the first year we find physics, zoölogy, botany, general chemistry, rhetoric and elementary French or German, and free-hand drawing among the studies required. In the second year there is botany, zoölogy, comparative anatomy, geology, comparative osteology, physics, qualitative analysis, and themes. It is certainly to be hoped that the medical teachers of the United States will not remain content with the very elementary examinations which are now demanded from those students who have not received a college education. The advantage of a previous college training is shown in some statistics given by Billings<sup>1</sup> of examinations conducted by the examining boards of the Army and Navy. Of those candidates who had a college degree 34 per cent were successful, and of those who had no such degree 28.9 per cent succeeded. It is interesting in this connection to note that, taking the medical schools of Harvard, Yale, the College of Physicians and Surgeons, and Bellevue Hospital, of New York, the University of Pennsylvania, and the University of Virginia together, 46.1 per cent succeeded, while for all the rest of the schools in a body 22.3 per cent succeeded.

One of the most prominent features of the new education is the character and amount of laboratory work which is now required by our medical schools. The new building of the Harvard Medical School, erected twelve years ago, showed the importance which its faculty attached to this means of teaching the student. Already the large addition of the Sears Laboratory has more than doubled the facilities of this department of the school. The University of Pennsylvania has felt the necessity of increasing the facilities for laboratory work, and has received a munificent endowment for its department of hygiene. The literature of this part of our educational system is already becoming voluminous. The recent reports of Vaughan and Holmes, in behalf of the work done at the University of Michigan and the College of Physicians and Surgeons of Chicago, respectively, show the interest which is taken in this subject in many of the Western schools. General chemistry forms so large a part of the first year's work in the Harvard Medical School that it is proposed to make room for other valuable work by making this study one of the requirements of admission. This course is already anticipated by most of the college graduates. The course on embryology and histology is at present required and lasts throughout the year. Students are obliged

---

<sup>1</sup> Ideals of Medical Education, 1891

to keep books in which drawings are made of the specimens studied, and these books are examined by the teacher. Those who do not possess microscopes are provided with them by the school, and the equipment of this department enables it to handle classes of 150 students. Prof. Minot, who conducts this course, urges the addition of a course on biology to the work of the first year, as it would not only enable the student to pursue many of his studies more intelligently, but would add greatly to the value of all original work done by the student or physician. The new four years' course has been so arranged that the technique of bacteriology comes in the first year. This is a time when the student has more time for laboratory work, and it paves the way for special work in the study of these organisms in connection with pathology, which is placed in the second year. I shall leave a more detailed statement to Prof. Ernst, who will have something to say upon this subject later. Bacteriology needs no special plea to-day. It can not even be regarded as a purely scientific study. No practitioner of medicine or surgery who emerges from one of our schools to-day should be considered properly equipped for his work unless he has been trained in such a laboratory. No physician can expect to unravel the secrets of disease without a practical knowledge of the demonstration of certain forms of bacteria, and there is certainly no better school for aseptic surgery than the bacteriological laboratory. The study of pathology at the Harvard Medical School<sup>1</sup> is conducted by Prof. Councilman, not only by lectures, but by demonstrations, recitations, and exercises in pathological histology. The latter course, which has hitherto been optional, is now obligatory. The relation of bacteria to disease is taught by the study of certain types of disease, as tuberculosis, suppuration, pneumonia, etc. Demonstrations are given twice a week of material obtained from the hospitals and from private practitioners. This is a laboratory exercise. Members of the class are called upon to study the specimens. He then carries around to the other members of the class and demonstrates and explains to them the lesions. Each student in this way has the specimen demonstrated to him. In the course on pathological histology the student is required to make drawings of the sections studied, and opportunity is given to a certain number of men who have gone through with the course in pathology to act as demonstrators the following year and to assist in teaching. Places are assigned in the pathological laboratory to a certain number of students who have done well in their studies, and opportunity is given them for special study or original investigation.

A type of laboratory course, which I think is peculiar to Harvard, is that on the application of bandages and surgical apparatus. It is a purely laboratory course, is given to students at the beginning of their second year, and is confined to a detailed study and drill in the practical part of such work. Bandaging is taught upon the living subject and a few wooden models. The feature of this course which is perhaps most valuable is the preparation and application of all the forms of stiff bandages. In this way every member of the class learns thoroughly the elementary part of this work before he begins to practice upon patients in the hospital, and no student leaves the school without becoming an adept in the application of the stiff bandage.

Another subject which is receiving more and more attention yearly is that of clinical instruction. The weakness of this feature of medical education was one of the glaring faults of the old system and arose out of the fact that hospitals were far less numerous than they are at the present time, and that from the necessities of the situation the independent origin of the medical school became a custom which has continued almost unimpaired to the present day. In Boston the medical school flourished for nearly one-third of a century before its teachers realized the impor-

---

<sup>1</sup> Bulletin of the Harvard Medical School Association, No. 4.

tance of this problem. A circular was then issued, in 1810, in which the statement was made that "a hospital is an institution absolutely essential to a medical school." Would that all teachers of that time had realized sufficiently that fact and had educated the public to recognize the necessity of such a close relation of the two. Many of the older members of this congress can remember the old-fashioned prejudice which resented the intrusion of students into the hospital wards. The theory of the trustee of that time was "this money was given for the cure of patients and not for the education of physicians." They could not be persuaded that the two interests were identical. The change of feeling in more enlightened times was indicated by the benefactor of the great Johns Hopkins Hospital. At the opening of that hospital in 1889 Dr. Billings showed the advantage of such an union in the following words:

It is well known to those familiar with the subject that the sick in a hospital where medical instruction is given receive more constant, careful, and thoughtful attention than do those in a hospital where no such instruction is given. The clinical teacher must do his best. Keen eyes will note every error in diagnosis, every failure in the results of treatment. Moreover, the very act of teaching clarifies and crystallizes his own knowledge; in attempting to explain, the dark places become prominent and demand investigation, and hence it is that those cases which are lectured on receive the best treatment. I need say nothing here on the other side of the question, the value of properly-trained physicians to the community and the necessity for hospital instruction in such training. Johns Hopkins understood all this, and specially directed that "in all your arrangements in relation to this hospital you will bear constantly in mind that it is my wish and purpose that the institution shall ultimately form a part of the medical school of the university."

The reaction in favor of clinical teaching is becoming daily stronger, and no school can hope to compete with the great schools of the country which does not have control of what is usually called "clinical facilities." This term must, unfortunately, still be used; for the number of schools which have hospitals of their own is yet exceedingly small. The union between the two is in most of our large cities becoming a more and more intimate one. Another immense advantage which the possession of a hospital gives to a faculty is the control of appointments. Most schools are now obliged to select their teachers from members of the staffs of hospitals in their city who have services at times of the year which enable them to teach. These individuals are appointed by laymen who have no knowledge and no regard for the necessities of medical education. Faculties thus placed are unable to select teachers of national reputation, as there is no appointing power which enables them to give such a person the material with which to teach. This is a grave defect in our system, and one which the leaders in medical education should not forget to impress upon the profession and the public. But while applauding the movement in favor of clinical teaching, it is perhaps well at the present time to consider whether systematic or, as it is usually incorrectly called, "didactic" teaching should be abandoned. The discussion as carried on in the medical journals appears to lean in this direction. A course of systematic lectures enables the teacher to cover ground which he would be unable to do even in a clinic most richly endowed with material. The method of handling the subject differs entirely from that adopted at the bedside, and in a well-regulated four-years' course I believe the systematic lecture should still retain a prominent place. Clinical instruction should be abundant, and of the most varied kind. Instruction of the class in small sections is a most desirable feature of this department. It involves a greater expenditure of time and an increase in the teaching staff and great ability as an organizer in the head of the department. It is the squad drill, however, which brings the student in most intimate contact with disease. To carry out these ideals necessitates a "plant" far in advance of that which the average school now possesses. No such enterprise can be undertaken without

that aid which has hitherto been conspicuous by its absence. I refer to endowments. The valuable paper of Dr. Bayard Holmes, already referred to, gives some interesting data on this subject. He says:

The productive funds in the hands of medical schools, both those connected with and those independent of universities in the United States, was, in 1889, \$249,200, while at the same time there was in the hands of schools of theology productive funds to the amount of \$11,939,631. The value of buildings and grounds used by medical schools at the same time was \$4,047,618, and the theological schools were accommodated with buildings and grounds valued at \$7,762,095. \* \* \* The medical schools had, in 1889, 12,238 students, who paid tuitions to the amount of \$763,761, while at the same time the theological schools enrolled 6,989 students. I am able to reinforce these figures by an abstract of the statistics for medicine, theology, and technology as reported to the bureau in June, 1892. The medical schools possessed buildings and grounds in 1892 valued at \$7,507,937, and productive funds amounting to \$611,214. Medical departments of State universities also received State aid in 1892 amounting to \$40,500, which, if capitalized at 5 per cent, would be equal to an endowment of \$810,000; making a total endowment of \$1,421,214. There were 16,731 medical students in attendance. The theological schools report productive funds amounting to \$17,599,979, and stated, at the same time, the value of their buildings and grounds was \$10,720,860. They had 7,672 students in attendance. Technological schools report productive funds amounting to \$13,229,940. These institutions received from State appropriations or municipal aid, in 1891-'92, \$747,504, which, if capitalized at 5 per cent, would be equivalent to an endowment of \$14,950,080; making a total endowment for schools of technology of \$28,180,020. There were enrolled in the schools of technology 10,921 students, about one-third of whom were in preparatory courses. It will thus be seen that the endowment of theology is increasing at the rate of about \$2,000,000 a year. The technological schools are well provided for, but medicine has scarcely raised its endowment, even at the most liberal estimate, to a million and a half.

Probably the available funds procured by our medical schools are somewhat larger than these statistics show, but they give the proportions which are needed to impress upon us how little financial encouragement medicine receives. When we realize what a valuable factor the medical man is in the rapidly increasing development of the territory of a vast and prosperous country like ours, it seems as if his claims to receive encouragement should be listened to. He does not build railroads or organize societies in new lands, but he is in the foremost rank of pioneers. With the complete equipment which our teachers can give him to-day he becomes a most valuable member of society. He protects the young colony from epidemics; without him State medicine could not exist, and States could not be founded on a basis which would insure prosperity. These ideas should be impressed upon our men of wealth and upon the State governments as well. In the meantime it is important that we should adopt as a principle in our new departure in education that the medical faculty should have personal control of hospital wards and management. Let this work begin in a small way at first, but with a view to future development. Such a change can only be brought about by a slow process of evolution. The sooner, therefore, the principle is recognized and adopted, the better. It is difficult for a prosperous school, which has abundant opportunities for bedside teaching, to realize this, but it can not develop beyond a certain point until it has established its own independence. I can not help believing that in this direction lies one of the greatest avenues of development of our system of medical education in the future.

## PAPERS READ BEFORE THE SECTION.

## THE IMPORTANCE OF PHYSIOLOGICAL CHEMISTRY AS A PART OF MEDICAL EDUCATION.

By R. H. CHITTENDEN, Ph. D.,

*Professor of Physiological Chemistry in the Sheffield Scientific School of Yale University.*

In this age of progression, when the attention of the medical profession is being directed toward a broader and more comprehensive system of medical education, it is well to consider some of the claims presented by physiological chemistry to occupy a prominent place in the medical curriculum of the day or, if not as an integral part of medical study itself, as a fundamental part of that preparatory training which all progressive minds in the medical profession consider as so important for the most complete and intelligent understanding of the science of medicine in its broadest sense. There can be, I think, no objection from any quarter to the general statement that biology, together with chemistry and physics, constitutes the best and most natural line of preparatory work for the medical student. Indeed, it may well be questioned, whether physics, chemistry, and a certain amount of biology should not form a necessary part of the training of any person seeking a liberal education. To be sure, the intending medical student may well pursue these subjects much more thoroughly than one who desires general training rather than special knowledge. The biological sciences, however, so closely underlie the science of medicine, are so plainly the substructure on which the latter rests, that one can hardly conceive of a broad and intelligent comprehension of the subject without a preliminary training in some one or more of the biological sciences. Just here, however, in order to prevent any possible misunderstanding, let me at once emphasize the fact that what is required first of all of a medical student, as well as of a student in any department of learning, is a broad and well-developed mind, trained to habits of thought and observation, endowed with the power of logical reasoning, and fully alive to the necessity for broad and liberal culture. This is obviously the first requisite, and it is folly to assume that a limited biological training, although valuable in itself, can counteract the defects or make good the deficiencies incidental to the lack of intellectual development. A boy fresh from the district school, or from the high schools of our cities, with his mind mostly unformed, is neither fit for the study of medicine nor of any other profession. What he requires first of all is mental training. We need not discuss here whether such training should be obtained through classical studies or through mathematics and the natural sciences. It is sufficient for present purposes that the need for general training be widely recognized. Let it be understood that the medical profession demands men of high intellectual attainments, broad and scholarly, and that there is no short road of preparation for medical studies, through biological or other channels, any more than for the professions of law, theology, art, or literature. Granting all this, as everyone interested in the future development of medicine must, we come back to our starting point, viz., that biology constitutes one of the most important, if not *the* important, preparatory study in medical education. Biology treats of the science of life, of the structure and function of living organisms, high and low in the scale. What more natural and appropriate, therefore, than that the student, aiming to make his life work the study and treatment of the diseased human body, should turn to the study of animal and vegetable forms in order to gain knowledge and experience of the general laws regulating life in all its phases. It is only by a

close scrutiny of the simpler forms of life that we obtain the requisite knowledge to unravel the complexities of structure and function characteristic of the more highly developed human organism. The broad line of demarcation, formerly drawn between the life processes of animals and plants, has been gradually growing narrower and more indistinct, until to-day we are forced to believe in the existence of essentially the same kind of protoplasm (i. e., containing essentially the same chemical substances) in animal and vegetable cells alike, and without regard to the position they occupy in the scale of life, whether in man or in the highest or lowest animals and plants. This naturally leads to the view "that definite fundamental chemical formations and changes are common to all living beings,"<sup>1</sup> and although there are many superficial as well as fundamental differences between the different classes and orders of animals and plants, yet it is evident "that many processes can take place according to a conformable fundamental type. Further, in the life processes of man these parallels are again found, whose simplest manifestation we perhaps follow with the least difficulty in the lowest organisms. We are thus brought to a definite unity in the original structure and processes of living existence."<sup>1</sup> "All living beings, of form and life phenomena the most widely different, appear to owe their fundamental structure to an original chemical organization, with properties common to them all,"<sup>1</sup> from which we can see direct gain to the medical student in the study of lower forms of animal and vegetable life. Further, as an indirect gain, it must not be overlooked that in such lines of biological inquiry the student, while acquiring a fund of useful information more or less directly applicable to his everyday needs, undergoes a training, the value of which can not be overestimated. His powers of observation are called into play, the habit of drawing deductions from observed facts, the noting of resemblances and differences, all tend to educate him in methods of exact work, and lead eventually to habits of self-reliance and a freedom from prejudice and preconceived opinions, which will prove of inestimable value in his after life of practice by the bedside. He learns to appreciate the significance of small things, and becomes thereby well trained in the essentials of accurate diagnosis in a manner which can not be imitated by text-book instruction in any branch of knowledge. He must be taught to observe accurately, and being possessed of reasoning powers soon acquires the habit of close and logical reasoning. All this, I take it, will be readily granted by the unprejudiced mind, but the question naturally presents itself here as to what is meant by or included under the term of "biology." We need not stop for a scientific definition of biology, for our interest centers rather in the interpretation of the word as applied to biological courses of instruction. Judging from the courses offered by most of our institutions of learning under the head of biology, the latter ordinarily includes more or less zoölogy and botany, with a comparatively large amount of dissection of typical forms. This is coupled with a certain amount of histology, and perhaps embryology, all being intended to constitute a more or less thorough presentation of the morphological side of biology. Less thoroughly presented, ordinarily, is the physiological side. To be sure, physiology is usually found as a part of the curriculum of a biological course, but seldom is it taught other than by text-book or with that degree of thoroughness characteristic of morphological instruction. Further, in those institutions where physiology is given a prominent place in the biological course, it is usually a one-sided presentation of the subject. It consists mostly of muscle and nerve physiology, with demonstrations of blood pressure and kindred experiments, designed to illustrate mainly the mechanical side of physiology. I would not be considered for one moment as saying a single word against such lines of

<sup>1</sup> Hoppe-Seyler's address on "The Development of Physiological Chemistry and Its Significance in Medicine."

physiological experimentation or instruction ; it is certainly of the highest importance and, in my judgment, is just what is needed in every course of physiological study. But what I would like to impress upon my hearers is that there is another side of physiology which, in this country at least, has not been cultivated as it should be, viz., the chemical side of physiology, or physiological chemistry. It deals with quite a different series of problems from those pertaining to so-called pure physiology, but I venture to say that the phases of physiological study and investigation it presents to us are as fundamental, if not more so, than any other single line of physiological work. By physiological chemistry I mean something more than the mere application of chemical analysis to a determination of composition. This, to be sure, is important ; but more valuable still is a proper understanding of the processes or lines of functional activity going on in the organs and fluids of the body, a rightful interpretation of which, however, must depend greatly upon our knowledge of the composition of the various parts of the body and upon the chemical constitution of the many organic substances disseminated through the organism. Physiological function depends largely, if not wholly, upon chemical nature and constitution, and although there is much that is vague and incomplete in our knowledge of the chemistry of the body, it is very evident that such chemical information as is obtainable is a necessary preliminary to all physiological study. Indeed, there is hardly a question, either in physiology or in the science or practice of medicine, which does not draw, to a greater or less extent, upon physiological chemistry for its solution.

As I am now addressing a body of physicians rather than physiologists, I can not do better than to repeat a remark of Prof. Hoppe-Seyler's, taken from an address on the development of physiological chemistry, as illustrative of the important position this well-known authority considers this branch of chemistry should occupy in the medical curriculum. "I can not understand," he states, "how at the present day a physician can recognize, follow in their course, and suitably treat diseases of the stomach and alimentary tract, of the blood, liver, kidneys, and urinary passages, and the different forms of poisoning ; how he can suitably regulate the diet in these and in constitutional diseases without knowledge of the methods of physiological chemistry and of its decisions on questions offering themselves for solution, and without practical training in their application." Again, Leube, the noted clinician, exclaims against the underestimation of physiological chemistry in medicine, and emphasizes the probability that the future success of medicine is dependent mainly upon the advancement of this branch of chemistry. In every medical school in the land there should be a well-appointed laboratory for the practice and study of physiological chemistry in every direction bearing on medical science. So, too, in every well-rounded biological course there should be ample facilities for instruction and experimentation, not only in pure physiology, but likewise in physiological chemistry, so that a broader and clearer conception of physiology may be obtained than is possible by the presentation of a single side of the subject. Obviously, in a course of biological instruction the morphological side rightly receives the first attention ; form and structure must be first studied, and thoroughly studied, but chemical composition and function are not to be entirely ignored. So, too, in medicine, the unsymmetrical development, especially of the last twenty years, by which the sovereignty of morphology has been attained, giving undue weight to anatomical methods of investigation, has reached its climax, and the clinicians even are now looking to physiological chemistry to aid them in unraveling many of the hidden processes of life, thus hoping to gain clues to clearer methods of diagnosis and more rational lines of treatment. And yet our medical schools are sadly lacking in facilities for teaching, as it should be taught, this important branch of science. Contrast, for example, the time allotted and the facilities afforded for studying

physiological chemistry with the time and facilities given to anatomy, histology, and pathology. The difference is appalling, and I say it with all due respect to the position these three subjects justly occupy in the medical curriculum, and with, I think, a due appreciation of the great gain accruing to medicine from the marvelous development of pathological investigation which has been witnessed during the last two decades. If, however, a small fraction of the time and energy given to these branches of medicine had been devoted to the simultaneous study and investigation of the chemical processes of the body in health and disease, I am sure equally important results would have been obtained, and as a final outcome a far more satisfactory explanation of many phenomena, for which anatomy, histology, and pathology alone have thus far given only incomplete or unsatisfactory explanations. It is from a judicious combination of the results obtainable by different lines of inquiry that the broadest and most definite, as well as the most accurate, deductions are to be drawn. From the very nature of things no one branch of biology, no one branch of medicine, is capable of affording as complete and satisfactory answers to the many general questions constantly arising as can be furnished by broader and more comprehensive methods of work.

Let us consider now for a moment some of the reasons for our belief that physiology and medicine are greatly indebted to physiological chemistry for their advancement. Obviously, in the first place, we must remember that our knowledge of the composition of the tissues, organs, and fluids of the organism, whether animal or vegetable, is derived entirely from chemical study and investigation. This is plainly self-evident; but when we consider how far-reaching are the facts thus obtained in promoting our understanding of the laws of growth of the human body, of the relationships of the various physiologically active and inactive tissues, of their development, of the character and extent of their activity, and of all the variations incidental to pathological conditions, we see at once the great importance of this knowledge in aiding us to a rightful interpretation of physiological laws. The great progress made of late years in our knowledge of the various digestive juices of the body, of their mode of action, of the character of the products resulting from the digestion of the various classes of food stuffs, of the conditions favorable and unfavorable to fermentation; these and many other things connected with the study of digestion in its broadest sense have all been accomplished as the result of long-continued and laborious experimentation in the domain of physiological chemistry; results that have not only helped to give us broader and clearer ideas of the physiology of digestion, but have made possible much of the advance in the diagnosis and treatment of disorders of the alimentary tract. Take from us our knowledge of the chemical composition of muscle and nerve tissue, and of the characteristics of the various substances entering into their structure, and what a blank would remain. Consider the importance of our ever-growing knowledge regarding the chemical changes going on in the two master tissues of the body, with their influence on heat production and on proteid and other forms of metabolism, and remember at the same time that, in spite of all that has been accomplished in the past, we have hardly passed the threshold of the possibilities opening up before us. Then, too, the whole broad question of nutrition in general, with its bearing on health and disease; the study of the urine and fæces, with the rich results such study affords as a means of diagnosis; the study of the liver and its secretion, the bile—all are in great part chemical problems, partial solution of which has already afforded results of inestimable value. Then consider for a moment the part chemistry has played in bringing about our present understanding of the manner in which microorganisms act in the animal body, with its bearing upon the whole question of infectious diseases, the discovery of the production of distinct chemical poisons by specific pathogenic bacteria, with the impetus this fact has given to the search for methods of producing immunity.

Then, too, we must not forget to recall the great aid chemistry has lent to therapeutics, giving us not only methods for the preparation of purer and more definite products, but opening up methods of studying the physiological action of drugs, which has greatly advanced the growth of scientific pharmacology.

In the brief time allotted for this paper we can not, however, even mention further specific instances of the way in which physiological chemistry touches and strengthens almost every department of medicine. I would that I had time to sketch for you a more detailed picture of this whole matter as it presents itself to my own mind, for I am sure that by so doing it would be possible to impress you more fully with the great need of broader and more liberal methods of instruction in this department of science, both as an aid to a better interpretation of biological laws and as a necessary part of a liberal medical education. And now allow me to say a word regarding the methods of instruction in physiological chemistry. Happily, the day is past when a medical student is compelled to obtain his knowledge of medicine from lectures, or even from books alone. Personal instruction and personal experience in the laboratory are essential requisites in any course of instruction that aims at the highest and best results. So, in physiological chemistry, there must be a well-equipped laboratory, where each student is provided with the necessary space and outfit for demonstrating the fundamental truths of chemical physiology. Instructors, too, must be provided so that at the most not more than fifteen men shall be under the guidance of one teacher, who shall thereby have time and opportunity to study and develop the material committed to his charge to the fullest extent. For men's minds, as you well know, are not all constructed on the same plan, and personal idiosyncrasies need to be recognized and dealt with in such a manner that each may receive the full benefit of the knowledge and training provided. A course in physiological chemistry worthy of the name should extend through at least six months, and preferably through a whole year, with an average of fifteen hours of laboratory work per week, interspersed with lectures, recitations, and demonstrations. Such a course of instruction as I have in mind can be advantageously taken only by men who already have knowledge of general, analytical, and organic chemistry, physics, anatomy, and histology, together with more or less familiarity with general physiology. You say, perhaps, that no medical student can afford to spend such an amount of time on a subject only indirectly connected with medicine. But I believe that to be a grave mistake, one that is in part responsible for the large number of half-educated men in the medical profession. As Dr. Billings, in a recent paper in the *Forum* on "Medicine as a Career," has well said: "This country is in no need of men possessing the diploma of doctor of medicine; it already has at least 20,000 more of them than it requires or can properly support; but it does need several hundred, say 1,000, more of properly trained physicians." An experience of eighteen years in a large university in teaching physiological chemistry as a part of a biological course having for its chief aim the preparation of young men for the study of medicine has convinced me that the time spent in such study is well spent, and that such a line of work can be advantageously made a part of the university or college curriculum, so that the intending medical student may have a fundamental idea of the scope and aim of physiological chemistry before he enters upon his medical course proper, just as he has, or should have, a knowledge of comparative anatomy, physiology, and general biology. But the medical school itself can well afford to establish a thorough course in this subject; indeed, no medical school at the present day can afford to be without such a course of study if it hopes to rank with the leading institutions of the land, or aims to provide instruction of the highest and fullest type.

And now just a word or two regarding the character of a course in physiological chemistry. There may obviously be different views upon this subject. I can

simply present my own. First, I believe that the student should be taught, in the laboratory, of course, the general reactions and properties of the various albuminous or proteid bodies, studying likewise their more common decomposition products, their relationship and chemical constitution, so far as known. Next in order come the various forms of epithelial and connective tissue, the student separating for himself and studying the various albuminoids which give character to the respective tissues, as the collagen of white fibrous tissue and the gelatin derived from it, the elastin of yellow elastic tissue, the so-called chondrin from cartilage, together with mucin and nucleo-albumin from the mucous tissues. Adipose tissue naturally comes next, and the several fatty acids are separated and studied, melting points determined, and the differences between the natural fats noted. This preliminary work, which involves much more chemistry than can be readily indicated by this short description, is followed by a study of the more important muscle tissue; the properties of muscle-plasma and muscle-serum are noted, and the various proteids and crystalline extractives characteristic of this tissue are prepared and examined. Myosin, the proteid of muscle clot, is especially studied, and its resemblance to the related globulins of blood-plasma noted. Again, it must not be forgotten that in order to make such a course as I am outlining of the highest value no opportunity should be lost to show the physiological bearing of all the results obtained; to try and instill into the mind of the student the idea that the facts of physiological chemistry have a wide application. Thus, in the chemical study of muscle tissue, for example, many lectures and recitations may properly be interspersed, sections, for instance, from Foster's Physiology making an admirable addition to the laboratory work; the object being to teach the student to make use of physiological chemistry as a means toward a broader and more accurate conception of physiological phenomena. Muscle tissue is followed by a study of nerve tissue, the various bodies especially characteristic of this tissue, such as lecithin, myelin, cerebrin, protagon, and cholesterin, being separated and their general properties and reactions ascertained. The chemical differences between the gray and white matter are also noted, the neuroglia, neuro-keratin, and brain proteids are studied, while chemical and anatomical relationships are compared in this as in all other tissues examined. The study of digestion is taken up next, the various secretions, salivary, gastric, pancreatic, and intestinal, being thoroughly examined. Artificial digestive juices are prepared, and their action on the various classes of food stuffs noted and compared, this serving likewise to illustrate the general action of enzymes or soluble ferments in distinction from the organized ferments. The many products of amylolytic and proteolytic digestion are prepared and separated, their chemical and physiological properties ascertained, and a thorough study made of both the chemical and physiological side of digestion in its broadest sense, it being the writer's custom at this point to have the students study and recite, in connection with their laboratory work, nearly all of Book Second of Foster's Physiology, which treats especially of the tissues of chemical action with their respective mechanisms, and of nutrition in general. In a similar manner the liver with its secretion, the bile, glycogen, and glycogenesis, the spleen, blood, milk, and urine are all studied, and the proximate principles giving character to the several organs and secretions separated and examined. Further, the metabolic activity of the hepatic cells, and likewise of the kidney cells, is demonstrated by appropriate tests, such as the synthetical production of hippuric acid through the agency of the cells of the tubuli uriniferi. The chemical changes incidental to respiration are also experimentally studied, and the detection of blood stains by spectroscopic and other methods duly considered. To the urine special attention is given, students being taught not only to make examinations of this important excretion but likewise to determine quantitatively the urea, uric acid, phosphates, chlorine, sulphates,

combined sulphuric acid, hippuric acid, creatinin, indican, sugar, albumin, and other abnormal constituents. Further, by daily quantitative examinations of the twenty-four hours' urine, opportunity is given to demonstrate many of the truths of nutrition or general metabolism, such as the influence of various forms of diet on the excretion of urea, uric acid, phosphoric acid, and combined sulphuric acid, the influence of drugs on proteid metabolism, etc.

This outlines very briefly the general character of a course in physiological chemistry such as I would see open to every student of medicine. To one interested in this phase of physiological work, such a course of study would naturally serve as a preliminary to more advanced work, which might readily deal with many interesting problems bearing directly upon medicine and medical practice. There is, in fact, almost no limit to the many questions constantly arising which demand the aid of physiological chemistry for their solution.

---

### METHODS OF TEACHING CLINICAL MEDICINE.

By FREDERICK C. SHATTUCK, M. D., of Boston, Mass.

Whether there is anything perfect in this world, I do not know. That it is possible to improve the teaching of clinical medicine, in this country at least, I feel quite sure; at the same time also I recognize the advance which is certainly being made, and am convinced that the advance will continue. We believe that the best is none too good for us, and propose to have it. To hasten and secure progress in the future it is well to understand and consider the past and the line along which evolution has worked to bring us where we are. We must also bear in mind the local conditions, with the advantages and disadvantages which they entail. The problems are: To make the best of what we have got, to get more, and gradually to surmount the bars to progress, whether these are accidental or inherent in the spirit and institutions of the country. It is easy enough to see the advantages of governmental control of the higher education, as exemplified in European countries. Professors are government officers; hospitals and laboratories are built and maintained by the state. All the parts which go to make a complete medical school should therefore work together like the parts of a machine, well oiled by national appropriations. But it is not likely that we shall see any general adoption of this system, or anything similar to it, in this country, even if it were desirable that we should. While the town or municipality properly insists on and provides for primary education with us, intelligent private liberality must in the future, as it has done in the past, provide in the main for the endowment of advanced and professional education. Laboratories of all kinds, including hospitals, cost so much to build and maintain that no medical school can pay its bills from the tuition fees of its students, even if a self-denying and devoted faculty is willing to forego all direct pecuniary returns. It is to the honor of this country and of American public spirit that there are good medical schools, the teachers in which have from the start adopted this unselfish plan of devoting every cent of surplus to improving the facilities for teaching. Without endowment it is impossible to provide all that is needed. Endowments will not flow toward proprietary schools which are exposed to more temptation than is desirable toward a lowering or half enforcement of standards. They will, however, flow to schools which are really parts of universities; and I believe that we can rely absolutely on the intelligent private liberality of our citizens to provide all that is required. But we must make our wants known, and indicate the means by which they can be best supplied. Everything comes to him who waits.

Allow me now rapidly to touch on the beginnings of medical education in this country and the manner of its growth. Roughly speaking, a century ago we became an independent people, full of vital energy, and with ample opportunities for its exercise in the development of a vast and rich territory. During the colonial days we looked to the parent country for professional education, as well as for many other things. With independence came an increased stimulus to provide more fully for ourselves. The medical school of the University of Pennsylvania had been already started. That of Harvard began in 1783, with three professors. Other schools gradually followed. Medical education before this was obtained entirely from a preceptor, whose students compounded his pills and draughts, read such books as he had, drove about with him on his rounds, and assisted him in many ways, even to the care of his horse perhaps. For many years after the establishment of medical schools clinical teaching remained in the hands of the preceptor. But it marked a distinct advance when opportunities were offered to enlarge the minds of students by coming to a city and hearing the leading facts and theories of medicine set forth by men of large and varied experience. Clinical teaching was then wholly derived from the private practice of the preceptor; systematic and didactic teaching formed the lecture course of the medical school. The number of men who could get their professional education, in whole or in part, in European capitals was very small. The medical school was a private institution, responsible to no one in theory, though the board of trustees of eminent laymen, chosen to add respectability and *éclat* to the enterprise, sometimes proved to be masters where they were intended to be servants. Or affiliation was sought with some existing university. But this connection was generally a loose one, the university practically doing nothing but conferring the degrees on those recommended by the medical faculty. The schools were essentially proprietary. This was the case at Harvard until twenty years ago, when the union became real and organic. It is only two years since the College of Physicians and Surgeons of New York became really a part of Columbia College. Medical schools antedated hospitals. The largest cities in the country one hundred years ago were small, the population was practically native, and there were very few poor requiring hospital treatment. The development of hospitals in this country practically is included within fifty years, when the stream of immigration began to change from a brook to a river. Medical schools being essentially proprietary, and being active only a few months in the year, hospitals were a separate foundation and grew up under separate management, a misfortune which, perhaps, could not have been avoided under the circumstances; but a great misfortune nevertheless, and one which still weighs heavily on the great majority of the schools of the country. Medical schools were founded by physicians, hospitals by benevolent laymen, always, it is true, with the active coöperation and oftentimes distinctly as a result of professional influence. But they were under separate management, and it was natural enough that laymen should consider the introduction of students in a hospital as a drawback rather than a help to the patients, and that they should be unwilling to hand over the hospitals to a proprietary medical school, which could give no guaranty of permanency or of reasonable freedom from selfish action. Under this mode of hospital foundation the service was divided up among the leading or most active medical men of the town or city. If a teacher had a service of three or four months, the duration of an old-fashioned lecture term, he was satisfied. Indeed he, in common with the non-teachers, preferred a short term, as allowing more time for private practice, the emoluments of which he required, as those of his teaching position were indirect and uncertain. Thus arose a second great drawback to clinical teaching; a drawback which is more felt now that the older schools undertake to furnish entirely, or in much larger measure than formerly, the bedside instruction of the old preceptor. In a word, then, the two chief difficul-

ties with which we have to contend in this country in developing first-rate and sufficient clinical teaching are the lack of complete union between medical schools and hospitals and the system of broken hospital service. Another and incidental disadvantage is the impossibility of calling clinical teachers from other places. In the purely scientific branches it is a matter of providing a salary; but the school which does not own its hospital can not provide the clinical teacher with a hospital service. It will, of course, be understood that I am speaking broadly. There are schools in this country which own their own hospitals and can regulate the terms of service therein. But I think I am safe in stating that with the possible exception of McGill University, in Montreal, there is not a single one of the leading schools which absolutely controls sufficient clinical material for the methods of clinical teaching which prevail at present, much less for such methods as we should aim to follow in the future. The Johns Hopkins will start with a clean slate on a proper system, and with every facility for the best and most thorough clinical instruction. All friends of medical education must watch its course with the greatest interest. Its success must stimulate other schools to make more of the advantages which they possess, and must strengthen their hands in the struggle to secure those which they still lack.

It must be added that in spite of the disadvantages under which we labor in this country as a whole, the practical working of things is not so bad as might be expected. The laymen who manage private and endowed hospitals are intelligent men as a rule, and are realizing more and more that the interests of their sick charges, as well as the reputation of their hospitals, are subserved by the instruction which is carried on within their walls. And I can see a current setting toward a diminution in the size of the staff and a consequent lengthening of the term of service. There is much more that might be said, and doubtless better said, on this broad theme of the relation of medical schools to universities and hospitals. It is a fundamental question. If we can secure and control further opportunities for clinical teaching, the subsequent details present no special difficulty.

To a brief consideration of these details I must now pass on. I do not know where and when the first chair of clinical medicine, independent of that of theory and practice, was established in this country, and this little paper is written far from any medical center or books. It is rather less than forty years since the chair was founded at Harvard, and my father was its first occupant. Since this time the increase in the amount of clinical instruction has been, on the whole, steadily progressive. In the twenty-five years which have passed since the writer began to study medicine the number of exercises per week in clinical medicine has been multiplied several times; and the four-years' course, the success of which must depend largely on clinical opportunities of all kinds, is bringing still further increase in amount with, it is hoped, some corresponding improvement in method. The clinical lecture to large classes in the amphitheater, which marked the commencement of instruction in clinical medicine, maintains, and always will maintain, a place. Much instruction can be imparted in this way, with economy of time to the student and of teaching force to the school. However careful and ample the drill of the individual student may be made I believe that the clinical lecture will survive. During a year a wide range of disease, as well as much of the variation of individual diseases, can be illustrated by patients, drawn both from the wards and from the out-patient department. The student is thus shown methods of diagnosis and treatment, his attention is called to the changes in structure and function which disease works in the living body, and the particular case can be made to illustrate general principles. But the work is done for the student, and must be done for him, in the main. The limits of an hour, and the enlistment of the sustained interest of the class as a whole, do not permit the drill of one or two individuals whose profit is largely at the expense of the main body.

In many of the schools of this country clinical lectures to a full class are given in sufficient number and of high quality. What, practically, all the schools need most is the clinical drill of the individual student and a close contact between student and patient. This implies a wealth of clinical material and a considerable number of instructors, among whom the class can be subdivided so that each can have the precious opportunity of observing and finding out for himself. The ward visit is a valuable means of instruction in rendering it possible to see and follow out diseases and cases of disease which can not well be transported to the amphitheater. But it is hard to make a ward visit profitable to more than a dozen students at once, and the management of an independent hospital is apt to look askance at a method which tends to increase and complicate the work in the ward in ways which it is not necessary to elaborate.

There is one feature in particular of the English system of clinical teaching which has always seemed to the writer most admirable. Each student must serve a certain number of months in the ward as clinical clerk, with certain cases, for the care of which he is responsible under supervision, and with all the details and course of which he necessarily becomes familiar. It is thus impossible for him to enter practice without any practical experience whatever; and, what is more important, he is forced to exercise his powers of observation for himself. The identity of school and hospital make this system easily possible. And yet it has not been attempted in European schools to any extent as far as I know. Anatomy can not be learned without dissection, chemistry without laboratory work. Nor can clinical medicine be learned in the best way without work in a hospital ward and out-patient room. It is possible that much use could be made of the sick poor at their homes under the charge of dispensary physicians, though there are practical difficulties in the way. I believe that along this line lies the first present necessity and opportunity for development. The recognition of the necessity is the first step toward the provision and utilization of the means. There should, again, be primary as well as advanced clinical instruction. In the new schedule of studies under the four-years' course now in operation in the Harvard school, this principle receives full recognition. The course in the second year is entirely separate from that in the third; that in the third will be more or less independent of that in the fourth year. Each student will have in his second year four hours a week; partly clinical lectures and demonstrations of semeiology and diagnostic methods, partly drill in small divisions in physical diagnosis, and partly ward visits in the hospital. The general scheme for the third year is to provide more advanced instruction in the wards and amphitheater, including therapeutics, as illustrated by the case or cases in hand. In the fourth year it will be the aim to make the work as practical as possible, and give the student opportunities to apply and fix the knowledge which he has already gained at the same time that he increases his stock by more intimate contact with disease.

Many years ago my father introduced an exercise in clinical medicine which has become popular and been adopted by other departments in the Harvard school, to which it is still, so far as I know, peculiar. It is called the "clinical conference." Each student in his final year is provided with a selected case, usually in a hospital ward, though sometimes in a dispensary district. He is expected to visit and follow up this patient, and write a practical paper on the diagnosis, prognosis, and treatment. A month or six weeks is allowed for the preparation of the paper, which is then handed in and which counts a fraction toward the examination for the degree. From these papers a selection is made, according to character and subject, and every week one is read by its author before the class and a number of instructors in the department. The reader is then subjected to criticism and question by his fellow-students and teachers. On the preparation of these cases much pains is bestowed, and I think there can be no question that the exercise is

a useful one. It is a matter of honor that the work on the case should be really that of the student himself. Under the four years' course, instead of one I hope that each student may receive a number of cases to look up in this way.

I believe that the future is bright with promise. The progress in a century has been enormous. At first we depended almost wholly on Europe or Great Britain for a first-rate medical education. Then students crossed the water for clinical advantages in hospitals, as these were non-existent or small in this country. Then a prime inducement was the chance for laboratory work—physiological, pathological, histological, and biological. Just as our hospitals have become second to none, so will our scientific laboratories. It will always be enlarging to the mind to visit foreign schools and study their methods. But it is no longer necessary for the attainment of an excellent equipment alike in practical and scientific medicine. We should bear in mind the fact that we have many possessors of large fortunes who can quickly see that in no way can they so usefully and with so much credit to themselves dispose of their surplus as by promoting medical education within as well as outside of hospitals. But the matter must be laid before them, as it can not be expected that they should be familiar with the requirements of clinical teaching. Who is so fit to explain the matter and can exert more influence than the family physician? Even if a teacher himself he can not be considered a specially interested party if he is an officer of a university, which goes on forever, and the management of which can be depended on to administer funds intrusted to it strictly within the purposes and wishes of the donor.

---

#### A DEMONSTRATION OF THE CÆSAREAN AND THE PORRO OPERATIONS.

By GUSTAVE ZINKE, M. D., of Cincinnati, Ohio.

This includes: (a) Preparation of the patient, her bed, and room in which the operation is to be performed. (b) What anæsthetic shall be employed? (c) What instruments and other articles are necessary for the operation? (d) Best time for the operation. (e) The operation itself. (f) The after treatment.

(a) Much will depend upon when, where, and how we find the patient; whether she be in the country, town, or city; whether she is already in labor, and whether her condition is such as to demand prompt interference, with little or no time left for preparation. But it should always be remembered that an aseptic condition of the mother, as well as of the operator, his assistants, and instruments, are most essential to success. Whatever little time the operator may have at his disposal should be employed in washing thoroughly, with soap and water, those parts of the mother's body which are concerned in the operation. The instruments, too, as well as the hands of the operator and his assistants, should receive thorough aseptic treatment. Antiseptics play an all-important part under such circumstances. The rest, such as cleansing the patient's body, changing her clothes on the bed, and cleaning the room, all may, in an emergency, be postponed until after the operation. If the case comes under observation at a period of gestation which gives time for preparation, say a few days, weeks, or a month or more, nothing should be left undone that may render the patient and her surroundings most favorable under the circumstances. If she can be removed to a special hospital, one devoted to abdominal surgery, it should be done. A general, especially a public, hospital should be avoided; unless it be provided with a building and an operating-room appointed and set apart especially for work of this kind. There can be no doubt the chances for recovery are much better in special hospitals. The patient's home, though the humblest in the world, is

preferable for the performance of the operation to a hospital filled with patients of every description and having but one operating room. The question of premature delivery is hardly to be considered here, since it is self-evident that if the patient can be safely delivered of a seven or eight months' child this procedure should be adopted in preference to Cæsarean section. As soon as the performance of hysterotomy has been determined upon, whether in a hospital or at the home of the patient, every precaution should be used for the purpose of insuring safety. Thus it will be well if the patient receive a daily vaginal douche ( $\frac{1}{4000}$  solution of bichloride), a warm bath, and a change of underwear for several days prior to the operation. Saline cathartics are the best for the purpose of securing free and daily evacuations. Rectal injections of tepid water will assist in relieving the bowels of their contents. On the evening before, the abdomen, mons veneris, and labia should be shaved, and an abdominal binder with perineal pad, antiseptically prepared, should be applied. The bed which she is to occupy after the operation should also be absolutely clean, the bedstead taken apart and thoroughly scrubbed, the mattress and bedclothes fumigated, then well aired, sheets and pillowslips rendered aseptic and antiseptic by boiling and subsequent dipping into a  $\frac{1}{2000}$  bichloride solution before drying. If she is in her own home the same apartment may be used for bed and operating room. The room is to be prepared as follows: If walls and ceilings are painted they should be washed; if papered, wiped; if neither, whitewashed or whitened. Windows and frames should also be washed and the floor thoroughly scrubbed and subsequently kept sprinkled with a  $\frac{1}{2000}$  bichloride solution. The temperature of the room should be kept between 60° and 65° F. for at least twenty-four hours prior to and between 70° and 75° during the operation. A temperature of between 80° and 85° is preferable, for the reason that the patient maintains her own temperature better, and consequently the breathing continues more regular, and the heart's action is less apt to fail. The operator, his assistants, and the nurse should be strictly aseptic. This means a bath and clean clothes in the truest sense of the word. No other patients ought to be attended by them previous to the operation. Instruments, sponges, dressings, and towels must be rendered aseptic and again sterilized before using. Operating gowns or jackets and aprons to be worn by the operator, assistants, and nurse should also be sterilized. An ordinary kitchen table, properly cleaned and supplied with an aseptic blanket or comfort, pillow, rubber and linen sheet, is amply sufficient for the purpose of an operating table. The patient should be dressed as "for the night," an undershirt and sleeping gown being all she ought to wear. On the morning of the operation no food is to be permitted, except, perhaps, a small cup of very light coffee and a small piece of toast. Some operators prohibit even this. Before or while the anæsthetic is administered from one-eighth to one-fourth of a grain of codeine or morphine may be given subcutaneously. Placed upon the table, her clothes are rolled up under her shoulders; the lower extremities are wrapped up in warmed, clean blankets, and after the antiseptic abdominal dressing, worn by her during the previous night, has been removed and her bladder emptied, towels wrung out in a warm bichloride solution are so placed across and along the sides of her body as to cover her clothes above and the blankets below. The abdomen remains exposed to the operator. Enough sterilized water should be on hand for all purposes. The hands of the operator and assistants are best rendered aseptic by the method suggested by Howard Kelly.

(b) The choice of the anæsthetic is left to the operator. After ten years of experience in operative work, both as assistant and principal, I have come to the conclusion that it is very satisfactory to begin anæsthesia with the use of chloroform, and, after the patient is unconscious, to continue with the A. C. E. mixture, suggested by Reeve, of Dayton, Ohio. When this is followed by a total abstinence

from food and drink during the twenty-four hours following the operation there will be but little, often no, disturbance from vomiting.

(c) Instruments and other articles necessary for the operation may be briefly enumerated as follows: (1) An ordinary scalpel and elbow scissors for the abdominal incision. (2) A grooved director. (3) A tongue and half a dozen hemostatic forceps (less may answer the purpose). (4) Ligatures of different sizes (silver, silk, silkworm-gut or cat-gut). (5) Needle-holder. (6) Sponges (antiseptic gauze or cotton may take the place of sponges). (7) Rubber tourniquet to throw around the uterus before it is incised (not absolutely necessary). (8) Abdominal irrigator (may not be needed). (9) Iodoform powder; iodoform or antiseptic gauze for dressing the abdominal wound. (10) Adhesive plaster. (11) Abdominal bandage and perineal pad. (12) Hypodermic syringe and whisky or brandy for subcutaneous injections. (13) Hot water bags or bottles.

(d) An all-important question is, What is the most favorable time for the operation? Without entering into a discussion of the subjects and citing the different authors and their reasons for selecting either a period immediately before, during, or after dilatation of the os, I will simply state that the most favorable moment for interference is, in my judgment, when the os is sufficiently dilated to admit of a ready discharge of the lochia. If the operation is performed before this stage has been reached the os will have to be dilated artificially. This must necessarily be deficient, to say nothing of the fact that it prolongs and complicates the operation. Still, there may be good reasons for operating earlier, as in the cases of convulsions, or hæmorrhage due to placenta previa or malignant disease of the cervix; or later, as in cases where the contraction at the inlet suggests the possibility of spontaneous or forceps delivery. The various steps of the operation will be shown upon the manikin:

The abdominal incision is made directly in the median line, about 6 inches in length, commencing immediately above the umbilicus, and continued toward the symphysis pubis. It is not absolutely necessary to make the cut directly through the linea alba. Pean and Tait prefer to penetrate the peritoneal cavity just to one or the other side of it. They claim it is difficult to bring and hold in apposition the two aponeurotic edges of the cut, and, if this fail, hernia easily results as a consequence; this can be obviated, it is said, by entering at one side of the linea alba. This argument suggests itself as plausible. After the peritoneal cavity has been reached, the incision is best completed and elongated by the elbow scissors. If it is the aim to eviscerate the uterus before incising it, a 6-inch abdominal opening will not suffice. But evisceration of the uterus prior to delivery of the child does not commend itself, because it necessitates a very long abdominal incision; again, it is difficult to turn out the uterus, even when the wound is 8 inches in length, nor is there much to be gained by evisceration of the organ at this stage of the operation. To prevent excessive hæmorrhage a rubber tourniquet may be thrown around the uterus sufficiently low that no part of the foetus may come within its grasp. The application of the tourniquet, however, requires the introduction of at least one hand into the peritoneal cavity. It is often difficult, and frequently impossible, to bring the tourniquet into position, and, after this is accomplished, its purpose may be defeated by that part of the foetus which presents at the os, especially if the membranes have ruptured previously. For these reasons, and the loss of valuable time, the tourniquet is not often employed by experienced operators. Hence, evisceration of the uterus, as well as the application of the tourniquet, may be safely omitted during the progress of the operation. After all hæmorrhage from the abdominal wound has been arrested, and three or four sutures introduced in the upper angle of the wound, the ends of which should be fixed by forceps and the loops withdrawn from the wound and retracted upwardly, the operator is ready for the uterine incision. The

uterus, now exposed by the abdominal wound, is to be palpated to determine whether or not the placenta is attached to the anterior uterine wall; if it is, the wall will feel thick, and the parts of the foetus will not be so easily outlined as when the placenta is not situated in this region. If only a section of the margin of the placenta be present, the incision should be made immediately outside of it. But when the placenta has its attachment more or less directly upon the anterior wall the incision should be made as nearly as possible in the median line, and from above downward. If the placenta is not present, this is easily done. The womb may first be punctured with a sharp-pointed scalpel and the opening quickly enlarged with a blunt-pointed, curved bistoury. The hæmorrhage which follows, though great, is not as excessive as might be supposed; but when the placenta has been so implanted that even its margin can not be evaded, there is nothing to be done but to cut through both structures and deliver as quickly as possible. The extraction of the child is best accomplished by taking hold of one or the other extremity. Some writers have tried to lay down the rule: "Always deliver the head first." Experience has shown that this is not always practicable. In a vertex presentation the hand of the operator would have to pass down over the head to lift it out of the wound. The instant the uterus is opened and the hand introduced, it contracts, the amniotic fluid escapes, and the cavity of the uterus, as well as the wound, rapidly diminishes in size; so that, unless the head is promptly and easily liberated before this occurs, considerable force will be required to deliver in this manner; so much so that there is great danger of increasing the length of the wound by rupture in a downward direction, an accident which ought to be avoided for self-evident reasons. When there is a large amount of liquor amnii in a vertex presentation, delivery of the head in advance may, perhaps, be free from difficulty; without it, or when the fluid has already drained off, and the uterus is firmly contracted around the child, no risk should be incurred or time wasted in this direction, but delivery effected by the feet. In breech presentations, especially dorso-posterior positions, the head readily finds its way out of the wound; not so, however, when the back of the child presents anteriorly, in which case, for similar reasons, it may be better to deliver by the feet. The only apprehension in a footling Cæsarean delivery is that the uterus may contract around the neck of the child before the head can be removed and thus the life of the child be sacrificed before it is extracted. When this danger is borne in mind, however, the uterine opening may be quickly enlarged by scissors or knife kept ready for the purpose. The same rules which guide us in the delivery of the after-coming head *per vias naturales* should here be observed; the object of which is to throw the smallest diameters of the head across the passage. During delivery of the child eventration of the uterus may be effected and the three sutures, previously introduced into the upper angle of the abdominal wound, closed by an assistant to prevent intestinal prolapse. The child delivered, the cord is tied in the ordinary way. The removal of the placenta may be effected by gentle traction upon the cord or, if adherent, the fingers may be introduced into the cavity and the organ separated from its attachment. The uterine cavity is then irrigated and dusted with iodoform powder. Proper suturing of the uterine wound is, next to strict asepsis, the most important features of success in this operation. It consists of bringing the wound together by both deep and superficial sutures. Silk, silver wire, and catgut may be employed for this purpose. Catgut, unless absolutely aseptically and antiseptically prepared, is dangerous for reasons evident to all experienced surgeons; silver wire, because it can not be absorbed, may become a source of irritation and annoyance; silk is, in the opinion of most operators, the most satisfactory, because it creates no irritation and its absorption is only a question of time. The deep sutures should be passed, half an inch apart, through the peritoneal coat and the musculature only. The inner

decidual surface must be avoided in every instance. The superficial sutures are passed between the deep sutures and grasp the peritoneal surface only, after the method of Lambert. The object to be attained is not only to bring the wound surfaces to close and exact apposition, but to cause its peritoneal edges to dip down into the wound, and thus secure a rapid union and prevent oözing from the uterine cavity. The uterus is now dropped back into the abdomen, which, if deemed necessary, may be irrigated with warm, boiled water. The abdominal incision is closed and the toilet made as in an ordinary ovariotomy. As a rule, no drainage tube is needed. A hypodermic injection of the fluid extract of ergot is then made and the patient placed in bed.

The after treatment is very simple: No food or drink during the first twenty-four hours. If food or stimulants are indicated they should be administered *per rectum*, because, if introduced into the stomach, vomiting will probably ensue, and this should be avoided, because of its tendency to disturb a favorable progress of the case. I know of no remedy or precaution which prevents or arrests the often very disturbing vomiting after an operation other than total abstinence from food and drink for a reasonable time after the operation. Opiates should never be given except for severe and continued pain. The bowels should be acted upon promptly if they do not move spontaneously after forty-eight hours. Saline cathartics are the best. The vagina should be antiseptically irrigated three or four times daily during the first few days, and less often thereafter. If all "goes well" the abdominal wound need not be disturbed nor the sutures removed until the seventh day after the operation.

In the presence of a body of medical men, most of whom are general practitioners, it is, I trust, pardonable to have entered into every detail of the operation; and, as many of the specialists and teachers in this department have never had occasion to see or perform the Cæsarean section, I have taken great pains and spared no expense or time to have a manikin constructed upon which this and other operations may be satisfactorily demonstrated for the benefit of students, practitioners, and incipient specialists of obstetrics and gynecology. It is the only manikin of its kind manufactured in this country, and I do not hesitate to say that it is equal to the best manikin made abroad, and in some respects even superior. Upon it the various capital, as well as minor, operations may be executed in a manner approaching real life. If the presentation of this manikin will be a help to the teachers of this branch of the profession its mission will have been fulfilled and the author amply repaid for his trouble.<sup>1</sup>

## A CONTRIBUTION TO THE STUDY OF MEDICAL EDUCATION IN THE UNITED STATES.

By BAYARD HOLMES, B. S., M. D., of Chicago, Ill.

An attempt is made to give a brief review of the origin of the American medical colleges, showing that they sprang from a desire on the part of ambitious medical men to advance in this way their own financial interests. This is shown to have been the case especially in a great number of the more recent schools.

The medical schools of the United States are divided into three classes: (1) Those that are under the exclusive control and support of State universities, (2) those that are under the control of university corporations or that maintain a nominal connection with such corporations, and (3) those that maintain no rela-

---

<sup>1</sup>To the firm of P. Goldsmith & Co., of Covington, Ky., who manufactured this manikin, I wish to express my sincere thanks for the time and patient effort they have so generously expended in its production. They are ready to supply any number of these manikins now, and will promptly fill all orders.

tions whatever to other educational organizations. The advantages and disadvantages of each class are considered separately. Illustrative examples of courses of study and a diagram showing the amount of instruction are presented. The tendencies of development are shown to have been as follows: (1) Medical theories; (2) medical theories plus demonstration of practice in hospitals, dispensaries, and clinics; (3) the application of the best educational methods in studying the theories of medicine and the same methods in the study of clinical material. The schools of the United States are now undergoing development in this last particular by the adoption of laboratory methods of study in all departments of anatomy, pathology, and clinical investigation. The needs of medical schools are shown to lie in improved methods of teaching rather than in better facilities for clinical demonstration; in new laboratories for individual and class instruction rather than in hospitals or laboratories for original research; in paid teachers of physiology, pathology, and clinical chemistry rather than in the extension of surgery, medicine, and obstetrics. Suggestions are made by means of model courses of study, and by means of rules designed to govern examinations and methods of measuring work. The possibilities and limitations of some of these methods are illustrated by the exhibition of class work actually accomplished. The relation of medical schools to hospitals is shown to be less intimate than the requirements of education and the needs of the patients demand. The position of medical courses in all but a few universities, where the control of the medical school is absolutely in the hands of the university, is shown to be less intimate and less rational than that of other departments in the following respects: (1) Admission to the medical school is allowed to the untrained and uncultured; (2) the courses in the medical school do not count in the elective courses for the bachelor's degree or the doctor's degree, save in a few schools; (3) there are no fellowships and no scholarships offered in medicine; (4) The relation of the professors in the medical schools to the trustees and to the treasury of the university are not upon the same basis as that of professors in other post-graduate departments. Relief is to be expected only in the endowment of medical schools either by private individuals or by the State. It is urged that the State should manifest as much interest in the health and food of man as in the health and food of hogs and cattle. Attention is called to the fact that at least \$750,000 is annually expended by the General Government on the agricultural experiment stations alone, while not a dollar is spent in medical education. Attention is called to the advantages of State university medical schools in their ability to coöperate with free hospitals supported by the State, the county, and the city, with State boards of health and experiment stations, with the administration of charities, with the administration of tenement and factory inspection, with the reformatory and penal institutions, and with all the many other varied activities of the general and local governments.

## THE POSITION OF BACTERIOLOGY IN A MEDICAL EDUCATION AND THE SCOPE OF THE INSTRUCTION.

BY HAROLD C. ERNST, A. M., M. D.,

*Assistant Professor of Bacteriology in Harvard University, Physician to Out-Patients at the Massachusetts General Hospital.*

In any consideration of the position that bacteriology should occupy in a course of medical education there are two points that must be discussed: First, whether it should come in as a special branch of instruction; second, how much, and when—that is, in what part of the course—should this instruction be given? It is often said that bacteriology can not be separated from pathology; by that meaning that any instruction given in this subject must come into close connection with

and be a part of a course in pathology, and that, in order to a proper understanding of pathology, bacteriology must be taught with it. The same thing may be said, however, and with equal force, of surgery; for no surgeon of to-day has a proper comprehension of any but the mechanical part of his specialty if he be not equipped with a knowledge of the properties of the microorganisms and their activity in the production of the infectious wound diseases. Without this knowledge the application of all the modern methods of aseptic and antiseptic surgery are but the result of rule-of-thumb methods, unworthy of the well-developed surgical mind. The same thing can be said in regard to clinical medicine; the facts that appear to have been developed of late years in regard to many of the diseases falling under this head render it absolutely impossible to intelligently understand and recognize individual cases or great epidemics of these diseases without a proper understanding of their causes, and, as is generally acknowledged, these causes lie especially in the vital processes of the bacteria. So also in hygiene or state medicine, the problems to be studied and solved have to do in many cases with the activity of the bacteria, and can only be rightly understood after a knowledge of these processes has been obtained. To take concrete instances: It may be said, and with much truth, that many of the advances in the management of wounds were made before the present knowledge of the bacteria was obtained. But they were not made before a theory of what their basis was was formulated, and they have been constantly amplified, simplified, and strengthened as the experimental knowledge of the bacteria has increased, so that to-day few of the younger practitioners have ever seen a case of hospital gangrene, which thirty years ago was not an uncommon entry upon the records of many a surgical ward. So, too, has the occurrence of septic diseases following surgical operations diminished in increasing ratio with the increase and spread of the knowledge of bacterial processes, so that it is almost a waste of time to call attention to these facts; but everyone knows with what confidence major operations are undertaken to-day, compared with the feeling of even ten years ago, and everyone knows, too, that the successful result of these operations justifies the confidence with which they are undertaken. This confidence is of course born of the knowledge that the precautions taken as the result of bacteriological research furnish strong safeguards against infection, which is to-day known to be the result of the entrance of a vital principle that it is, theoretically, possible to exclude at all times. Indeed, so far is this extended that, speaking theoretically again, it may be concluded that when infection does occur it is present because of some unseen loophole in the measures taken to guard against it, and it is no longer ascribed to climatic or telluric influences, as used to be the case, although, of course, such influences are not to be entirely excluded. So great, indeed, has been this advance that few of the younger men in our profession even know what Listerism was in its original form, and fewer still would know the uses of the elaborate instruments that were constructed to carry out its principles; instruments that our honored president first brought into the amphitheatre of the Massachusetts General Hospital not so many years ago, and which formed part of the impulse resulting in the great perfection of surgical methods obtaining there to-day. Here, too, should be mentioned the great work done by the obstetricians, for by this branch of the profession were the great principles of infection early applied with tremendous success; so much so, indeed, that it is not an uncommon thing now for a medical student to pass through his instruction in obstetrics without seeing a single case of puerperal fever; and it can never again be said, as did an old writer:

I arrived at that certainty in the matter that I could venture to foretell what women would be affected with the disease, upon hearing by what midwife they were to be delivered or by what nurse they were to be attended during their lying-in; and almost in every instance my prediction was verified. (Gordon, 1795, quoted by O. W. Holmes, *Medical Essays, Contagiousness of Puerperal Fever*. Houghton, Mifflin & Co., 1888, p. 103.)

So much for surgery. Less tangible results can be claimed for clinical medicine, but, as it seems to me, solely because of the infinitely greater complexity of the problem presented, not because the results thus far gained do not apply as directly to the management of cases of medical as of surgical disease. It would be absurd to say that one is not better fitted to manage cases of disease produced by bacteria, after a knowledge of the action of these bacteria has been gained, imperfect as it yet is and must continue for years to be, for what we already know is of great importance, if only it be perfectly applied; and the promise of what we shall know in the near coming years is of greater importance still, for the management of individual cases, for treatment, and for self-protection, as well as the prevention of the spreading of infectious diseases. It needs only to mention the most destructive of these, tuberculosis, to call an illustration to mind. Thirty years ago the infectious nature of this process was not generally acknowledged, and even Villemin's experiments failed to make that knowledge general. Since the discovery and study of the microörganism concerned in its production it has been possible to give advice and to formulate rules for our patients, based upon scientific knowledge, that must surely have tended to prevent the spread of the disease by reason of the careless distribution of the infectious matter coming from the patient. In other words, we have learned the scientific lesson that the infectious material in this disease, when seated in the lungs, is contained in the sputum; knowing that, we know how to control its spread. The same thing is true in regard to many other diseases, and the knowledge thus gained enables us to handle them with greater confidence and precision than heretofore; typhoid fever and cholera, with their infectious material in the intestinal discharges, and pneumonia and diphtheria, with theirs in the expectoration, are common examples. Indeed, it is not necessary to go further in the way of illustration, for the slightest thought given to the matter will call to everyone's mind instances of what is meant. So far as the treatment of specific diseases in individual cases is concerned, it is true that, as yet, but little of wide applicability has been obtained. Diagnosis, in certain most important cases, has been greatly helped, however. It is now possible to give the patients affected with pulmonary tuberculosis a chance for their return to health in that most important period of the disease, the so-called "pre-tubercular stage," a period extending over weeks or months, in which the physical signs may not furnish a basis for a positive diagnosis, but where doubts may be set at rest by the microscope. The bacteriological diagnosis of cholera and diphtheria are extremely important factors in the management of these diseases, and medico-legal questions demanding settlement by bacteriological methods are becoming more and more frequent as the importance of these methods are becoming known to the legal profession; also, the possibility of treating disease by methods resulting from and forced upon bacteriological research is becoming more and more prominent, and certainly these methods and the experiments leading up to them can not possibly be properly understood without some definite knowledge of bacteriology. The results obtained in tetanus, both in the laboratory and in the clinic, in pneumonia, diphtheria, and streptococcus infection, give such promise as to lead every medical man to desire to know something of the work upon which they are based. Even tuberculin, great as the failure to fulfill unjustifiable expectations was, seems to offer later results, in some of its modifications, that warrant hopes for the future and more favorable development in regard to it. At the least, it must be said that in the direction of the study of the bacteria and their products lies the greatest promise for advance in our knowledge of the etiology and management of disease now open to us. Naturally, in a subject of such far-reaching importance and so new to investigation, dealing with processes that are so delicate in nature and complex in completion, mistakes have been made and will be made again; but surely the sum total of results for the last ten years is something

to be proud of and of such value that it can not be neglected in any plan for well-balanced medical instruction.

Turning from clinical medicine to that branch which has to deal with problems of the general health of the people at large, the same intimate connection between bacteriology and many of these problems is then found. The general principles governing the development of the bacteria must be well understood by public health officers in order that they may properly discharge their duties, and persons competent to carry on an effective manipulation of these microorganisms must be at command for the proper investigation of subjects constantly demanding it. The volumes of the reports of the Massachusetts State board of health bear constant witness to this, as do those of other States and countries that have appreciated the importance of the developing facts of scientific investigation. The instances in which work of importance has been carried out in this direction are almost innumerable. That showing that the milk of tuberculous cows may contain the bacilli of the disease, even if the udder be apparently unaffected (done under the auspices of the Massachusetts Society for Promoting Agriculture and supported by parallel investigations in other countries), is one instance; the great work being done upon the filtration of water and sewage, the study of the nitrifying organisms by the German, French, and Massachusetts boards of health is another; and the reports of the national bureau of animal industry furnish many more. All of these results, and many others like them, are of necessity spoken of with more or less elaboration in any instruction that may be given in surgery, medicine, hygiene, physiology, or pathology, they form a part of all such subjects, but in no one of them is there a proper place for the fundamental instruction necessary to a proper comprehension of what the bacteria are, or what their importance in connection with disease may be. This is as true in bacteriology as in regard to anatomy, without a specific knowledge of which no medical curriculum is complete. That bacteriology can not be properly included under any of the present divisions of medical instruction seems also to be almost self-evident; to include it under the head of pathology shuts out at once a consideration of that part of the subject that relates to general hygiene and the broader subjects of the fermentations; while, if it be included under the head of hygiene, the limitations of the subject are again closer than its natural scope demands. Biology, from the standpoint of the general scientist, would of course include bacteriology, but here, instead of being too narrow, the danger would be that the extent of the instruction given would be too broad. For it is always necessary to remember, in laying out a course of instruction for medical students, that the important things for them to know are, first of all, those that can be practically applied in the management of disease in human beings, and that then should follow whatever may tend to make these practical things easier of comprehension. The facts of general biology are of great importance for the sum of human knowledge, but so many of them may be ignored for medical purposes that it would seem to be inappropriate to speak of biology where bacteriology alone is what it is desired to teach. Lastly, and perhaps more important from a practical point of view, the necessity for some sort of systematic training in bacteriology is made manifest almost daily in hospital work. The idea that ready methods of staining are all that are needed to enable the house officer to make bacteriological diagnoses is a very common one, and leads constantly to disastrous failures or mistaken conclusions. Ready methods are meant only for the expert, and can only be properly applied by him; to teach them to the beginner is sure to lead to misinterpretation. Perhaps no better illustration of what is meant can be given than that of tuberculosis. Rapid methods for demonstrating this organism are in constant use, and are taught to beginners everywhere, so commonly, in fact, that no single protest is likely to be of any avail against it; and yet my own experience and that of the gentleman working with me have shown conclusively that

there is no method of staining that may be constantly relied upon except the old one of Koch. Of course it is true that some of the others will demonstrate the bacilli in most cases, and when they do no more can be asked. But when the organism is not shown by these methods one is not justified in saying that it is absent. Now, this is an exceedingly important point for the patient, and yet it is one that the student is almost certain to lose unless he has been brought along by proper gradations to realize the use of what he is doing in attempting to stain the bacilli of tuberculosis. What sort of instruction, too, can that have been that will permit a senior house officer to attempt to get middle cultures in gelatine so hard and dry as to be able to turn the edge of an ordinary scalpel, or to wonder why a similar fresh medium does not remain solid and show expected peculiarities of development when planted in a breeding well? Experience shows universally that these and similar blunders are the constant results unless the student has a foundation of systematic training in the best methods of bacteriological work before being trusted with these shorter methods that should never be employed except after much training, if at all. Therefore, because the subject seems part of so many others, and because in no one of these others does there seem to be a fitting place for systematic instruction in the principles and methods of bacteriology, it has seemed best, in the minds of many experienced instructors, to set aside a special department in the medical course for the special study of this branch; and the example set a few years ago by one or two of the most progressive medical schools of this country is being rapidly followed, until to-day there is a special department of bacteriology, or special instruction in that subject, offered by a large majority of those of the better class. So that the question seems to have been fairly well settled already that, in the minds of those most competent to judge, there is a necessity for specific instruction in bacteriology for the complete education of the modern medical man; and this instruction is offered with more or less completeness.

It has been a matter of some interest to me to see how far this instruction is given in this country, and to that end I have looked over the published announcements of a number of medical schools that happened to be in the hands of the secretary of the Harvard Medical School and that were kindly loaned by him for the purpose. They are all of them announcements for the year just closed or just opening, and contain, therefore, as recent information as can be obtained. They are also, all of them, of schools that require a graded course and three terms of instruction preparatory to the conferring of the medical degree; they represent, therefore, the better class of medical instruction as given in this country. A summary of the results obtained in the study of these announcements shows the following interesting facts: There were 68 schools included in the number examined. Of these, 38 have no special officer of bacteriology, while 30 have an officer of some sort, ranging in rank from the full professor of bacteriology down to the simple assistant instructor in the same. Of these 30 schools that have special officers of instruction there are 19 that have but one, 7 that have two, 2 that have three, 1 that has four, and 1 that has five. When the study of the number of these schools that offer special instruction in bacteriology is completed we find that it sums up 50, leaving but 18 out of the whole number that do not offer or require some special instruction in the subject that we are considering; and closer search shows that of these 18, 8 are irregular or women's schools (all but 2 of this sort that were in the original number). From this it appears that there is a rather remarkable showing; that over 72 per cent (without the 8 spoken of, over 83 per cent) of these schools should be offering special instruction in this branch of medical science, when less than ten years ago it was not thought of as even a possible part of medical education. But further investigation shows even a more important point still; that in this number of schools in which advantages of special

study are offered, 14 of them (a little over 20 per cent of the whole number) make a regular course and examination in bacteriology a part of their course for the medical degree. Another notable thing about this is that out of the 50 colleges offering instruction but 3 of them announce lectures alone; all the remainder speak of more or less elaborate and prolonged training in special bacteriological laboratories. This is as it should be, for no real knowledge of the bacteria, such as the medical man should have, can be given by didactic lectures alone; actual manipulation is the only means by which this branch should be taught. That it should be taught as a separate branch in all well-balanced courses of medical instruction seems to be demonstrated. How it should be taught, that is to say, how much special instruction should be given, and in what part of the course, is the second branch of our inquiry. It will easily appear, from what has already been said, that there are two ideas of the subject to be considered: First, in this branch, as in all others, how much is necessary for the intelligent instruction of the average medical man? This much should be given to all medical students. And second, how much should be taught of the great experimental problems opened up but still unsettled by results obtained in this branch of medical science? Under the first heading falls naturally the study of the facts upon which the principles of sterilization and disinfection are based, as well as the application of the aniline dyes and the special adaptation of the microscope to this work. To these are to be added certain well-established methods of cultivation, and the study of certain of the commoner forms of bacteria, both parasitic and saprophytic, both as observed in the laboratory and in the clinic. In other words, each student should be obliged to know as much of the life, history, and methods of observation of the bacteria as will make it possible for him to understand references to them in other parts of his course, on the one hand, and, on the other, to know the common forms of clinical application of methods of diagnosis. This much it seems necessary that every medical student should know. On the other hand, inasmuch as a medical course may properly have for its object the development of something beyond the average practitioner, advantages should be offered to such individuals as develop a taste for the work and a desire to push further in the study. Such advantages as these can be very well offered in the form of an elective course that the student may or may not take, according as his taste and impulse guide him, but the elective should contain much that is manual and should consist largely of laboratory work carried on by the student himself. In this work should be studied, besides the more minute investigation of the subjects included in the regular course, such questions as the bacteriological diagnosis of cholera and diphtheria; questions that can be determined only by means of culture methods combined with the microscope, not by the microscope alone. Lastly, there should also be offered to those few who have time and ability opportunities for original research along some one of the many paths that this new science has opened up; paths as yet untrodden, but leading with pleasant promise to unknown goals. How this special instruction may be given may be best illustrated by a short account of what is done in this line in the department of bacteriology in the Medical School of Harvard University. There are there offered three grades of instruction, and the effort has been to make these cover, as far as possible, the three grades spoken of above. There is, first, the required instruction, consisting of a course given in the second term of the first year and ending with an examination which every student is obliged to pass before taking the degree of doctor of medicine. This course consists of eighteen hours of lectures and eighteen hours of laboratory work for each student and, so far as the laboratory work is concerned, is designed especially to make the student familiar with certain of the simpler methods of manipulation and staining, such as are in common use and are generally needed being those selected. The lectures cover a theoretical explanation of the processes carried on

by the bacteria, and a preliminary explanation of their importance in the various changes produced by their activity, and are illustrated by the microscope, cultures, and elaborate lantern slides.

The laboratory course covers the following subjects: (1) Method of making cover-glass preparations; use of the aniline dyes; cover glasses made and stained. (2) Explanation of plate cultures and reason for their employment; importance of sterilizing the hands and the difficulties in the way; the hands are washed as thoroughly as may be and then plate cultures are made from them. (3) The plate cultures are examined (colonies are counted); test-tube cultures and cover-glass preparations are made from some of the colonies. (4) The group of suppurative bacteria is taken up; cultures and cover-glass preparations of several of them are made. (5) Diphtheria, illustrating peculiarities of shape; colonies and staining; cultures are shown and cover-glass preparations are made. (6) Cultures and sections are prepared (these organisms being used to show a class differing from the true bacteria). (7) Pneumonia; cultures, cover glasses, and sections (to show the non-unity of a disease until recently supposed to be of a single origin). (8) Gonorrhoea; cover glasses prepared (illustrating important facts of arrangement and employment of aniline dyes). (9) Tuberculosis; cultures, sections, and sputum (illustrating peculiarities of staining).

The principle object sought for in laying out this laboratory work was to bring in as many practical illustrations of important facts in regard to the bacteria as the time at command would allow, and the result seems to have shown the success of this endeavor. The students enjoy the work, and there has not any complaint been heard, except that there was not enough of it. They came to the course after a good drill in the ordinary methods of handling the microscope and the study of normal histology, and before they had come under instruction in general pathology or clinical medicine. The next opportunity that this same set of students will have offered to them will be the elective course that is given in the first term of the fourth year, meaning from the last week in September until the first week in February. This course covers the same ground, and more, and consists of lectures combined with the laboratory work; by that is meant that there will be no special didactic lectures out of the laboratory. At the beginning of the exercise enough time will be taken to thoroughly explain the work laid out for the day, so that the student may understand the principles upon which that work is based, and then each man will complete the practical work set aside for the day. The completion of this course will give the student a very good idea of the essential points in this important branch of investigation and will make him competent to go on with a line of special research, if he desires to do so. This course is open to graduates in medicine, and a similar one is given during the summer of each year. Last, and perhaps not the least important, are the facilities offered for special research. These facilities are in a separate laboratory, consisting of a large room divided into a number of smaller ones that are set aside for those desiring to carry on a long series of investigations. There is a special advantage in this, in that there is no disturbance from beginners, who never work in this laboratory at all, all of the instruction spoken of in the two first courses being carried on in a separate or preparatory laboratory, well removed from this. All of the best and most recent appliances for scientific work are procured as they are needed. There are animal rooms and cages for the isolation of inoculated animals, separate operating, culture, sterilizing, and wash rooms, with a special chemical room for the study of alkaloids of bacterial origin. The features of the instruction as given at the Harvard Medical School are: (1) The use of two large, thoroughly equipped laboratories solely for bacteriological work, one of these laboratories being reserved entirely for advanced students, the other for beginners. (2) The grading of the work in this department, by means of which the student

may easily prepare himself; first, with enough knowledge to utilize the clinical methods learned here; and second, to carry on special investigation if he wishes. (3) The special encouragement constantly given to efforts in the direction of scientific investigation. So far as can be learned from the public announcements, there is but one other school in which equal attention appears to be given to this special branch of medical instruction, by that, of course, meaning instruction to undergraduates, and this is the University of Michigan. In the medical department of this institution there are required courses in bacteriology extending over twelve weeks and every day. Four hours a week are devoted to lectures and recitations in the first half year. Bacteriological analysis of water is especially taught. Advanced courses are offered to graduates who have taken these others, and special courses in the study of the ptomaines and leucomaines are given as well. Experience has taught that the best time for introductory studies in bacteriology is in the earlier part of a medical course, and that more elaborate work should come late in that course or after it is completed, and this is precisely what is done in the two schools in the country that lay most stress upon the matter.

I hope I have made it clear that there certainly appears to be a demand as well as a warrant for special instruction in bacteriology to medical students, aside from what must come to them in most of the larger branches of medical education. The time when the instruction should be given, and its amount, while necessarily modified by circumstances, should be about as indicated in the discussion of what is being done.

---

#### DISCUSSION.

Dr. F. G. NOVY, of Ann Arbor, Mich. The position of bacteriology in a medical course and the extent of instruction which should be given is a matter of so much importance that I deem it desirable to briefly touch upon the work as carried on in the medical department of the University of Michigan. The year in which bacteriological instruction is to be given deserves careful attention. While in some medical colleges the work in bacteriology is reserved for the senior year, or even for a post-graduate course, in others it is given in the freshman year. We have tried the course in each of the four years of our curriculum, and have found that the most satisfactory results are obtained when it is given in the first year. One great benefit which a student derives, or should derive, from laboratory instruction in bacteriology is the habit of cleanliness, patience, and perseverance. From his work in the laboratory the student learns of the chances of contamination and the dangers of infection. The familiarity with methods of personal disinfection and the sterilization of apparatus and instruments fits him for his subsequent work in medicine and in surgery. The study of bacteriology by lectures and in the laboratory, therefore, properly belongs to the first part of a medical course, before the student enters upon the study of diseases and on his clinical work. The relation which the subject bears to the subsequent work in medicine is the same as that possessed by chemistry, anatomy, and histology, and it should therefore be carried on in conjunction with these subjects. The instruction in bacteriology in this university is twofold. During the first semester of the year didactic lectures, four times a week, are given on the morphological and biological properties of bacteria; on their chemical products, and on their relation to fermentation, putrefaction, and disease. The infectious diseases are considered and so also are the principles of sterilization and disinfection. The course in laboratory work covers a period of three months and is given three times during the college year. The entire afternoons of every week is devoted to the work. Each student therefore spends four hours each day, for three months, in practical work in bacteriology. The preparation of the various culture media, the study

of a large number of saprophytic bacteria and bacteriological examinations of air, water, and soil, precede the work with the pathogenic microorganisms. Every student isolates, cultivates, and studies each microorganism by himself, and in this way acquires the carefulness in manipulation and the confidence in the methods which it is necessary to have before entering upon the study of pathogenic bacteria. I am not in sympathy with the plan of instruction, unfortunately only too often followed, which on the plea of danger removes the study of the pathogenic bacteria to the senior year, or even later. The place to study the bacteria of disease is in connection with and subsequent to the elementary work on methods and on the ordinary bacteria, and if this preliminary work is properly done there need be no fear of infection. The practical value of the laboratory work in bacteriology begins with the study of the pathogenic bacteria, and for that reason this study should be made to follow the preparatory work and should be made as thorough as possible. In the course as given in this university from six to eight weeks are devoted to the study of pathogenic bacteria, fungi, and animal parasites. The students make their own inoculations on animals, perform the post-mortem examinations, and isolate the pathogenic bacteria from the tissues, thus demonstrating to themselves the relation of microorganisms to disease. The detection of bacteria in the fresh tissues and in sections, as well as their isolation and the study of the pure cultures, is given careful attention. In this way are studied all of the well-known pathogenic bacteria, including the anaërobic forms, as those of tetanus, symptomatic anthrax, and malignant edema.

#### PRELIMINARY MEDICAL EDUCATION IN THE UNITED STATES.

By WILLIAM T. SEDGWICK, Ph. D.,

*Professor of Biology, Massachusetts Institute of Technology, Boston, Mass.*

The fundamental requirements of sound preparation for all kinds of professional education may be drawn from Galen's admirable saying that "the best physician is also a philosopher." The blending of technical perfection with the philosophic mind constitutes the ideal of all professional attainment; and the problem of preliminary medical education is simply how to aid the medical schools to the utmost in their strivings toward this ideal. We shall see that preliminary medical education should minister to both of the ends and that it is desirable to establish the basis of a philosophic mind while laying the foundations for professional education.

Persons still young have had the opportunity of witnessing a remarkable change of opinion concerning preliminary medical education in the United States. It was formerly believed that the only thing to do was to get a good general education, and the more general it was the better. Professional education was regarded as a kind of necessary evil, or at least as something of small value from the educational point of view and, therefore, to be postponed as long as possible. Accordingly, students who desired the best preparation for medical studies were kept as long as possible in the college, giving their attention to miscellaneous, and especially to so-called "disciplinary," studies, most of which were avowedly irrelevant to all professional subjects, and therefore (so the theory ran), especially desirable for those who must afterwards be "cabined, cribbed, confined," in professional studies. But with the advancement of more varied knowledge, the development of men of culture and capacity outside the colleges,<sup>1</sup> and especially with the con-

<sup>1</sup>"It is not by academically trained men, as a rule, that the great physical discoveries have been made. Those who have made these discoveries have broken away, so to speak, from the traditional life of a student and a scholar; have quitted the books and betaken themselves to the study of things." J. G. Fitch, *Lectures on Teaching in the University of Cambridge, England*, p. 357, 1880.

quests of science, it has dawned afresh upon educators that there is no royal road to learning. It is perceived that common sense, order, insight, exactness, imagination, truthfulness, reverence, and the love of truth, whether old or new—these and other elements of the philosophic mind can be developed in the same person (if at all) in any one of many ways. This change in the educational point of view has gone on until in the present state of opinion the tide is setting powerfully in the direction of definite and relevant preparation for all kinds of professional work as opposed to miscellaneous, indefinite, or irrelevant preparation. Nowhere is this more strikingly evident than in preliminary medical education. Some of the prophets, however, cry out that this will result in a set of possibly deep but inevitably narrow specialists; that if man's general culture be not cared for early by others he will never care for it himself, perhaps never get time to care for it. Culture, on this theory, would seem to be a kind of drug which, if not administered early, will fail to take effect. For myself, I do not believe in this theory. As long ago as 1865, Dr. Jacob Bigelow, one of the ablest physicians of Boston, and one of the most cultivated, advanced, and thoughtful men of his time, in an address upon the "Limits of education" before the newly founded Massachusetts Institute of Technology, dealt with it as follows:

I have dwelt on the importance of a special and well-selected path of study as leading to success in education and not less in subsequent life. Nevertheless the necessity of absolute confinement to this path is to be accepted with great modifications. A youth with vigorous and varied powers will not easily restrict himself to a beaten track, but as his mind grows he will become discursive in his aspirations. He will carry along with him not only the adopted or select pursuit which has enabled him to serve, to impress, or to excel others, but he will also be prompted, both before and after he has grown up, to entertain himself and to extend his relations with those who surround him by devoting his surplus time, which his very success has given him, to the enlargement of his sphere of occupation.

Some persons, no doubt, on any system of education, will become mere specialists, and mere specialists are better than mere dilettanti, for they are usually not only very happy themselves but extremely useful to the rest of mankind. Many dry-as-dusts have arisen on the old system, which in its time has borne much knotty and unmellow fruit. A still more vigorous denial of the charge that early specialization in education necessarily means narrowness or failure we owe to Prof. George H. Palmer, professor of philosophy in Harvard University, in his important papers on "The New Education" (Boston, 1887):

The popular distrust of specializing is sure to grow less as our people become familiar with its effects and see how often narrow and thorough study, undertaken in early life, leads to ultimate breadth. It is a pretty dream that a man may start broad and then concentrate, but nine out of every ten strong men have taken the opposite course. They have begun in some one-sided way and have added other sides as occasion required. Almost in his teens Shakespeare makes a specialty of the theater, Napoleon of military science, Beethoven of music, Hunter of medicine, Hugh Miller of rocks, Faraday of chemistry, Hamilton of political science. The great body of painters, musicians, poets, novelists, theologians, and politicians are early specialists.

But the best of all answers and the keynote of the whole tendency of education to-day is Goethe's:

Willst du in's Unendliche schreiten?  
Geh' nur in's Endliche nach allen Seiten.

There may be always two kinds of preparation for professional studies, one germane to the future profession, the other foreign to it, or at least irrelevant. Both kinds, the germane and the irrelevant, are still to be seen. The old-fashioned college still sends men to the medical schools irrelevantly prepared. The elective system, itself the chief monument of the new education, suggests and favors but does not compel relevancy in preparation for professional studies. The group system compels it.

The history of special or relevant preparation for medical studies is the history of heroic attempt of disinterested educators to aid in the improvement of medical education. Twenty-five years ago candidates for medical schools were entirely destitute of relevant preparation. Those who came from the higher institutions of learning were supposed to have well-disciplined minds and much general information; but they were nearly as ignorant as their fellow-students from the farm, the factory, or the workshop of any of the subjects germane to medical studies, such as physics, chemistry, and natural history. Many of them have made excellent physicians, but there is reason to believe that they might have achieved even greater success and in greater numbers if they had been better prepared for the study of medicine. The establishment of sharply defined courses of study preparatory for the professional study of medicine at the Sheffield Scientific School at Yale, the Johns Hopkins University, Cornell University, the Massachusetts Institute of Technology, the Lawrence Scientific School, and other institutions of learning in which an effort has been made to fit men expressly for the medical school, has been an attempt to help on medical education toward the lofty ideal of Galen, and to multiply the number of those physicians who shall be philosophers also. It was because educators saw the raw material which medical schools had to work upon and determined to improve it. They saw or believed that they saw how, by imparting a liberal education of the hand, the eye, and the brain, largely through subjects more or less germane to medical studies, they might send to the medical schools candidates, already bachelors of arts or of science, trained in laboratory ways, informed with respect to nature, including living nature, and especially human nature, with some loss of breadth perhaps, but with an immense gain of depth. They hoped that the medical profession, which was loudly talking of the low standard of medical education, would meet them half way and make some adequate recognition of a difference between men well prepared and men not well prepared on admission. But in this they were at first disappointed. Too often the graduate well prepared had no warmer welcome at the medical school than the graduate not well prepared or even unprepared. One year in some other medical school even of low grade gave an uneducated man precedence over both; and so, except in one or two cases, the attempt has languished chiefly for lack of encouragement on the part of the medical schools. But a change is at hand or has already come. The better medical schools, in a sincere attempt to compel the unprepared candidates, who are generally in a large majority, to remain with them long enough to obtain a sound professional training, within a very few years have doubled the period of required medical education. But in doing this they have sacrificed without mercy the candidates who had taken pains to prepare themselves well, and also those who had obtained collegiate or scientific education before beginning their professional studies with no very definite idea of what they were doing, but with a most praiseworthy wish to get a sound preliminary education. No exception has been made and no provision for these, "the flower of our youth," except admission to the medical school by diploma instead of an easy examination. The result is likely to be, and the danger is, unless some amendment can be made, and that very soon, that many who might otherwise be more liberally prepared, and whom it is most desirable to have so prepared, dismayed at the prospect of an excessive cost of time and of money, will avoid both of these by passing from the secondary school to the professional school. One of the important secondary schools in Boston is offering in its prospectus the logical alternative of these conditions, viz., "Preparation for all universities, scientific, law, and medical schools." It is fair to suppose that the possibility of directly proceeding to any one of these is kept before the boy, and, what is equally important, before his parents. It must require some argument to convince a doubter that he should take two of these (usually) four-year courses instead of one, so long as he observes

that in many medical schools no important difference is recognized between beginners well prepared and beginners ill prepared. It is the difficulties to which this curious state of affairs leads that have moved Prof. Welch, dean of the Johns Hopkins Medical School, to remark that there are, in respect to preliminary medical education, "very serious and important difficulties peculiar to the system of education in this country."<sup>1</sup> Prof. Welch believes that the main trouble is with the colleges "which keep the students two years after the study of medicine should begin." This may be true; but the trouble is not wholly with them. It comes quite as much from the rapid doubling of the period of required medical education from two to four years without due regard to the needs of the most desirable students. But we must turn from the disease to the remedy. That which Prof. Welch proposes, as the contribution of the Johns Hopkins University, has the distinction of compelling the nongraduate to come up to the standard of the graduate candidate, and the further immensely important advantage that the candidate shall not only offer evidence of possessing the philosophic mind, but also a considerable foundation for professional attainment, inasmuch as he must have had a thorough, if elementary, training in the natural sciences of physics, chemistry, and biology, as well as in modern languages. This is not only an interesting concession to the educational Zeitgeist and a great gain for the student who has wisely prepared himself, but also a graceful recognition of the value of the efforts of those universities and scientific or technical schools which have so long sought to help on the higher medical education. The practical difficulty, however, remains and is even aggravated, namely, the element of time and money. The medical education proposed by the Johns Hopkins University, so far as outlined at present, will inevitably be very long and very costly. Educators may well raise the question whether it is not unnecessarily long and too costly, and also whether the Johns Hopkins University, which has already done and still aspires to do so much for medical education, is absolved from educational criticism by the bare statement of its dean, "We fully realize that the number of students who will meet these rigid requirements is not likely to be large." In the John Hopkins scheme the greatest hardship falls upon ordinary college students, "the flower of our youth," who during their blossoming have not seen fit to take, or have had no chance to take, physics, chemistry, and biology as required for admission to the Johns Hopkins School. These, with diplomas in their hands, must yet be turned away, for fruit, not "flower," is wanted. But such will not long be the case; and sound educators will rejoice that this has been done, for it will compel the colleges to classify or even group their courses preparatory to medical studies, and will in so far give point and system to their work. If it has now become recognized that the college, the university, and the scientific school may thus powerfully aid the medical school, may we not hope that the medical schools will themselves take one more step and encourage their candidates to come prepared not only in the subjects mentioned for their professional welfare, but also in physiology, general anatomy, and physiological chemistry to the end that one whole year of time and money may be saved for the now overburdened medical student? Of the two years which need to be cut off from the period of complete medical education, including preliminary education, it is only fair that one shall come from the medical school and the other either from the colleges (or similar institutions) or from the secondary schools. There are signs that the latter saving will not long be delayed. The former might easily be accomplished; is, I believe, already accomplished in the Harvard Medical School, the pioneer in these reforms, by simply granting advanced standing to those who can pass off on entrance the first-year subjects. In the prospectus of the Johns Hopkins Medical School there are no strictly professional subjects in the first year; and if this school should hereafter allow those

---

<sup>1</sup> Address before the Johns Hopkins University, June, 1893.

who are prepared in these to omit that year and to enter the second year of the medical school a great incentive will be offered to universities, colleges, and scientific or technical schools to save that year for their graduates by allowing them to take these subjects during some part of their four-years' course. For these institutions the gain in sharpness of definition, in enthusiasm, in seriousness would be immense, and the moderate sacrifice of educational idols involved would not be irreparable. For the medical schools the practice would even then be merely that which already prevails and works admirably in another group of professional schools, the scientific or technical schools, namely, to allow graduates of colleges and other scientific or technical schools to enter by diploma; to excuse them from all subjects in which their proficiency is satisfactory and allow and require them to take whatever professional studies they are prepared for and have not had. In all essential respects a medical school is a technical school; that is, a school in which a practical profession is taught, as Prof. Huxley long ago observed. Is there any good reason why it should not act accordingly and abandon the idea that any special halo surrounds the subjects pertaining to medical education, making it indispensable that physiology, general anatomy, physiological chemistry, or even pathology, must needs be taught in technically medical schools if any virtue is to be in them? When this state has once been reached the problems of preliminary medical education can be left to settle themselves by a kind of natural selection and survival of the fittest.

---

#### THE AIMS AND METHODS OF MEDICAL EDUCATION.

By WILLIAM C. DABNEY, M. D.,

*Professor of Practice of Medicine, etc., in the University of Virginia, and formerly President of the State Board of Medical Examiners of Virginia.*

The ultimate aim of medical education is to fit those who enter upon the study of medicine to prevent and cure disease and to relieve suffering. For the proper accomplishment of this work several things are necessary. (1) A sufficient development of the faculty of observation and the reasoning faculty to enable the person to judge of cause and effect and to draw proper conclusions from ascertained facts; (2) a knowledge of the work done by others directly or indirectly connected with medical matters; (3) an ability and willingness to work; (4) a just appreciation of the extent and character of the work which they undertake and of the responsibility which they assume.

I propose to consider in this paper the importance of these different subjects—"avenues of training," if I may use such an expression—and shall endeavor to show by what methods the mental training and discipline of a medical student may be best accomplished. Let me say in the beginning, however, that in the consideration of the requirements of those entering upon the study of medicine I have in view the great numbers who yearly enter our lecture rooms with very moderate intellectual capacity, scant literary training, and often the most deplorable ignorance of the gravity of the task and the responsibility on which they are entering. These are the men and women who treat the great masses of our people, and who need, therefore, the best medical education and training which can be given them. I recognize the fact, so encouraging to all who are interested in higher medical education, that among those entering upon the study of medicine there is from year to year a larger and larger number whose minds have been broadened and enlightened by preliminary training, and who are thoroughly alive to their own responsibility and the needs of humanity; but the medical teacher should always keep in view the needs and requirements of the average medical

student, and not of the favored few, who, by reason of natural ability or superior preliminary training, will overcome all obstacles and far outstrip their less favored associates.

I have stated briefly the chief requisites of those entering upon the study and practice of medicine. The next question which presents itself is, What are the best means of attaining these requisites? I shall consider this question under the following headings: (1) The preliminary studies calculated to develop the faculty of observation; (2) the preliminary studies calculated to develop the reasoning faculty; (3) the order in which the various branches of medicine should be studied; (4) the time which should be given to laboratory work and lectures each day; (5) the value and importance of the didactic lectures and of daily recitations; (6) the objects and methods of clinical instruction; (7) the importance of a high standard of graduation in medical colleges, with especial reference to the character of the work done by the graduate in after life.

(1) THE PRELIMINARY STUDIES CALCULATED TO DEVELOP THE FACULTY OF OBSERVATION.

No argument would seem to be necessary to show the importance of a habit of careful observation of details in the study and practice of medicine, yet it is surprising to see how many persons well educated in other respects are woefully deficient in this. It would take me beyond the scope of this paper to consider, except in the most cursory manner, the means by which the faculty of observation is to be developed before the study of medicine is entered upon. Yet it is a matter of the utmost importance, especially at the present time, when so many institutions of learning are arranging the studies in their academic courses with reference to the subsequent professional studies of the student. The academic studies which seem to me of most importance for this purpose are geology, zoölogy, and botany, especially the last of the three. All of these branches of study necessitate the most careful observation of details, but botany is of especial value because of its intimate connection with bacteriology. When the study of medicine itself is entered upon chemistry, anatomy, histology, and bacteriology are the studies which necessitate careful observation, and are therefore of the utmost importance, not only on account of their intrinsic value, but as a means of mental training and discipline as well. There are, of course, other subjects which necessitate careful observation, indeed all branches of knowledge do, but those which I have named seem to me the most useful for developing this faculty in the medical student.

(2) THE PRELIMINARY STUDIES CALCULATED TO DEVELOP THE REASONING FACULTY.

The academic studies which are valuable for developing the reasoning faculties and which are of especial value to those who propose to enter upon the study of medicine are natural philosophy and logic. I do not mean to exclude mathematics from this list, but I have not named it specifically because it is a subject studied by all to some extent at least, and the value of which for purposes of mental discipline is universally recognized. Nor would I underrate the value of the languages, ancient and modern, not only on account of the wide field which they open up for instruction and entertainment, but because of the broadening influence which they exert upon the mental faculties. I am old-fashioned enough even to believe in the study of Greek, not only for its own sake but for its influence upon the intellectual faculties as well. Still, it seems to me that no other academic studies are as useful to develop the reasoning faculties of the student who proposes to enter upon the study of medicine as those which I first named; natural philosophy

and logic. The medical studies proper which are most useful for this purpose are physiology and pathology viewed in its broader aspect. I shall speak of this more in detail when I come to consider the value of didactic lectures.

(3) THE ORDER IN WHICH THE VARIOUS BRANCHES OF MEDICINE SHOULD BE STUDIED.

There is but little difference of opinion nowadays on this point, and it is almost universally conceded that some knowledge at least of chemistry, anatomy, normal histology, and physiology is absolutely necessary before the student can profitably engage in the study of the so-called practical branches. A few colleges, I believe, still expect the student to begin his medical studies with the daily attendance upon lectures on anatomy, chemistry, physiology, materia medica, obstetrics, practice, surgery, and perhaps a number of special subjects, but the number of these schools is growing rapidly less, and it is almost certain that in a short time all medical schools which are worthy of the name will adopt a graded course and give the student some time for study outside of the lecture room.

(4) THE TIME WHICH SHOULD BE GIVEN TO LECTURES AND LABORATORY WORK EACH DAY.

Not many years ago the students in many if not most medical schools were expected to attend lectures from 8 or 9 A. M. till 5 or 6 P. M., with one hour's intermission for dinner, and then to make their dissections at night. It is hard to conceive how the intellectual faculties of a student could be developed by this process. Mental confusion and physical fatigue would combine to retard rather than aid the development of these faculties. Three hours a day at most, it seems to me, is all the time that should be required of the student so far as listening to didactic lectures is concerned, and scarcely any more time should be given to laboratory instruction if both didactic lectures and laboratory instruction are given the same day. From four to six hours more, the time depending on the physical strength and mental training of the student, might be profitably spent in reading carefully in some good text-books the subjects of the lectures of the day and in comparing what has been seen in the laboratory with the teachings of those who are especially skilled in laboratory work. I do not speak here of clinical instruction; that subject has already been considered by Dr. Shattuck, and I will allude to it briefly a little later on. I need only say just now that it seems to me far better that the undergraduate should see a few cases daily and study those cases well than that he should have his mind crowded with difficult subjects, none of which can be properly digested.

(5) THE VALUE AND IMPORTANCE OF THE DIDACTIC LECTURES AND OF DAILY RECITATIONS.

There is at present a manifest tendency to do away in great part with the old-fashioned didactic lectures, and to substitute for them laboratory and clinical work on the one hand and the reading of judicious text-books on the other. Nor can it be denied that the change has been of immense value to medical education; but I am firmly convinced that on many branches of medicine didactic lectures, if properly given, are of great value as a means of education; that is, as a means of making men think and reason for themselves. For example, in the study of practice of medicine, with all the excellent books on the subject, none of them can or does explain the connection between causes, morbid anatomy, symptoms, etc., as is done in the didactic lecture; nor can an author emphasize in a text-book the points which may be of especial moment without making the book of inordinate length. I would offer an earnest plea, then, for the retention of the didactic lecture

as a means of instruction, of teaching men to think, not to the exclusion of other methods, but as a valuable adjunct thereto. Then there is another means of instruction which I believe to be of inestimable value, but which, unfortunately, can not be thoroughly applied in large medical schools; I mean daily recitations on the subject of the previous lecture. These recitations are a means of instruction both to teacher and to pupil; the teacher learns from them what points he has failed to make clear, and the pupil is taught not only what he has failed to catch before, but something far more important than that; the necessity for careful and thorough study and preparation. And much as I value the didactic lecture as a means of instruction, or rather of education, if I were compelled in my own teaching to abandon it or the daily recitation I would unhesitatingly discard the didactic lecture, for in the course of the recitations nearly all the explanation needed could be given.

#### (6) THE OBJECTS AND METHODS OF CLINICAL INSTRUCTION.

There are two objects to be attained by clinical instruction. The first, which is of great importance to the student, is the method of conducting the examination of a patient; and the second is to learn the symptoms and signs of diseased conditions. For the attainment of these objects it is essential that the student should not only see examinations made by others, but that he should see and hear and feel for himself. It is equally important, too, that the student should have clear views of what he does see and hear, and for this reason it seems to me far better that the undergraduate at least should see but few cases a day, and should be required to study them thoroughly, both at the bedside and in the text-books. Another point seems to me of the greatest importance in connection with clinical instruction, namely, that the student should have been thoroughly drilled in the principles of medicine before he begins to study cases, so that he can understand the significance of the various symptoms and signs and their connection with the morbid changes in the body. For example, how can a student understand the passive hyperæmia and dropsy of advanced cardiac disease who knows nothing of the anatomy and physiology of the heart and vessels, and how can he apply the proper treatment unless he has studied the pathology of the process and the action of drugs?

#### (7) THE IMPORTANCE OF A HIGH STANDARD OF GRADUATION IN MEDICAL SCHOOLS WITH ESPECIAL REFERENCE TO THE CHARACTER OF THE WORK DONE BY THE GRADUATE IN AFTER LIFE.

If I may judge from my own observation and the conversations I have had with a number of physicians who are interested in medical education, the importance of a high standard of graduation on the subsequent work of the student is not appreciated as I am satisfied it should be. It goes without saying that a man with very scant knowledge of medicine is not a suitable person to intrust with the health and lives of his fellow-creatures; but it is usually thought and often said that the defects and deficiencies of early training will be corrected by the experience of subsequent practice. Doubtless this is true in a measure; but there is another side of the subject which I believe to be equally true and of vast importance in medical education, namely, that the graduates of a school having a high standard of graduation will have a higher aim and do better work all through life than those who have had equal advantages in all other respects, but who have received their medical training in a school which considers a high standard of graduation unnecessary. Of course there are many exceptions to this rule; but, as I stated at the beginning of this paper, I am considering the educational needs of the great mass of medical students and not of the comparatively few of exceptional ability. My

attention was first called to this matter in 1885, when the graduates of many different medical schools came before me, as a member of the State board of medical examiners of Virginia, to stand their "State examination." It was a matter of profound astonishment to me and to my colleagues on that board to see the superficial character of the answers given to many of the questions by men of good sense, fair general education, and graduates of schools having admirable facilities for instruction and whose faculties would compare favorably with any in the world. I well remember the surprise depicted on the faces of some of the young men who were rejected, and the statement made by some of them that they had never been taught that "all those details were necessary in medicine." The superficial character of the answers sometimes required may be judged of also by the questions asked. I remember, for instance, in an examination on anatomy lasting three or four hours one of the six questions given the student to answer in writing was, "Describe the alimentary canal and its appendages." Now, Mr. President, how can a young man of average capacity be expected to learn thoroughness when the questions given him on examination are of such a character that only the most superficial answers can be given? How can earnest, painstaking, careful, and thorough work be expected of him in after life, when his training has been such as to encourage the reverse, and that training has been received from men of acknowledged ability and experience? I need not call attention to the necessity for a high standard of graduation as an evidence of the student's medical knowledge (or ignorance) when he comes up for examination; yet when graduates of respectable schools gravely state, as was done to our Virginia board, that "the post-partum artery should be tied to control post-partum hæmorrhage;" that in case the carotid artery is cut the physician should "keep the patient quiet and watch him close;" that "60 grains of atropine is the dose by the mouth, but 20 grains will do hypodermically"—in view, I say, of these answers, a little more care, it seems to me, is often desirable in testing the amount of medical knowledge possessed by the candidate for graduation. In conclusion, then, I would plead most earnestly for a higher standard of graduation, not only because it necessitates more knowledge of medical matters when the student graduates, but because it gives him a keener sense of the gravity of the duties which he has assumed and of the responsibilities which rest upon him.

## LA HIGIENE CEREBRAL Y EL EJERCICIO DE LA INTELIGENCIA.

Por el Dr. LUIS E. RUIZ,

*Catedrático de Higiene en la Escuela Nacional de Medicina de México, Director del Hospital Juárez, Secretario de la Sección de Medicina Pedagógica, y Representante del Estado de Hidalgo en el Congreso Pan-Americano.*

La vida con salud es el resultado de la armónica y regular actividad de todas las funciones, lo cual lógicamente advierte, que el ejercicio de las facultades es indispensable condición para permanecer sanos; pero este ejercicio ha de satisfacer dos condiciones higiénicas fundamentales: ser desempeñado por todas las funciones y proporcional en cada una. Solo de esta manera la integridad del ser humano es completa, pues á su bondad estática se une su corrección dinámica y de hecho en la vida se realiza el hermoso apotegma: mens sana in corpore sano.

La observación y la experiencia de consuno nos atestiguan con la irrefutable elocuencia de los hechos y su científica coordinación, que si malo es el quietismo de las funciones, porque viene la torpeza de las facultades, no es menos nocivo el exagerado ejercicio de ellas porque acarrea la atrofia. Luego el primero de los bienes, la salud, exige en nombre de la diosa Higia el moderado funcionamiento

fisio-psíquico. Pero si de esta consideración, puramente médica, que nos hace aconsejar saludable y total ejercicio, pasamos á otro orden de ideas ya del dominio pedagógico, ya del económico y social, muy fácil es convencerse de que la actividad de nuestras facultades es el único eficaz medio que poseemos para satisfacer nuestras necesidades, puesto que estas solo se cumplimentan con actos, que no son otro cosa sino variadas intervenciones de nuestras facultades.

Así pues, si las necesidades económicas de nuestra situación social, nos obligan á trabajar, si las exigencias de la salud han menester regularizado movimiento, y si el deseo del bienestar individual exige el ejercicio como condición indispensable de perfeccionamiento, tenemos que convenir en que la actividad de nuestras funciones todas, es condición precisa y conveniente para nuestra vida completa. Pero no basta ver con toda claridad, á la luz de la higiene y la pedagogia, que el ejercicio es factor para la salud y requisito de perfeccionamiento, sino que es indispensable precisar el como de este ejercicio. Por otra parte, estas consideraciones no van á referirse á todas las funciones, cuyo conjunto constituye la vida, sino especialmente á la más humana de nuestro ser, á una de las más importantes y más complexas que posee el hombre, á la actividad del cerebro, al ejercicio de la inteligencia. Esta función psíquica, verdadera antorcha de la especie humana, tiene dos modos fundamentales de actividad: adquirir conocimientos y elaborar-los. Por esta circunstancia las facultades especulativas, más que ninguna otra función, necesita la correcta actividad de todas las otras. A la inteligencia, más que á otra actividad, se aplica el axioma pedagógico expresado así: "El correcto ejercicio de las facultades superiores exige la integridad completa de las inferiores." Si la respiración es defectuosa, la inteligencia se entorpece; si la circulación no se hace bien, los actos intelectuales no se ejecutan correctamente; y el concurso de la alimentación es de tal manera valioso para los fenómenos mentales, que gráficamente un inteligente professor ha dicho: "Dime lo que comes y te diré lo que piensas." Y á semejanza de esto podríamos ir señalando el enlace y la dependencia de la inteligencia con las demás funciones; pero baste saber que si la inteligencia acumula conocimientos, estos en su mayoría vienen precisamente por los sentidos, y tan cierto es esto que el incomparable Aristóteles, exagerando un poco la verdad, dijo: "Nada hay en la inteligencia que no haya estado antes en los sentidos."

Por último, los movimientos ya generales, ya parciales, influyen de tal manera sobre las labores intelectuales, que en multitud de casos la inactividad muscular acarrea la pereza mental y por el contrario, el exagerado ejercicio de los músculos trae aparejada señalada torpeza del intelecto. La inteligencia, como las demás funciones de relación, tiene períodos de actividad y períodos de reposo, durante los cuales, más que ninguna otra, por la naturaleza de su funcionamiento ha menester descanso completo, pues solo con este requisito conserva su salud, aumenta su vigor y es capaz de agigantar su perfeccionamiento. El sueño es el reposo para nuestro espíritu y por lo mismo siempre que vayamos á disfrutarlo, debemos procurar todas las comodidades, ya de silencio y ausencia de luz, ya requisitos higiénicos del lecho y ya que antes de entregarnos á él no experimentemos por nuestras labores, musculares principalmente, grande fatiga. De esta manera, y teniendo cuidado de que la duración del sueño sea en todos los casos suficiente para el reposo y descanso cerebral, es indudable que habremos asegurado la base higiénica para el mejor ejercicio de la inteligencia. Mas este ejercicio tiene su más valioso campo en la escuela, puesto que la evolución mental que vamos á determinar, mediante la enseñanza, para que sea del todo propicia al éxito de nuestra vida completa, es absolutamente necesario que se ajuste tanto á los preceptos higiénicos, que han de conservar incolume su salud, como á las reglas pedagógicas que aspiran á perfeccionar facultades y á inculcar conocimientos. Si la educación puede y debe empezar desde la cuna, la instrucción jamás ha de

iniciarse organizada antes de los siete años, pues quien á esta fecha se adelante obliga al cerebro á un trabajo prematuro, comprometiendo su salud, y hace infructuosos los esfuerzos intelectuales, tanto más estériles, cuanto más laboriosos y abstractos.

La actividad inagotable del niño y su insaciable curiosidad están demostrando que sus órganos necesitan ejercicio, sus facultades empleo; pero su volubilidad característica, la superficialidad de que todos dan pruebas, señalan al mismo tiempo el camino que se debe seguir para enseñarlos. Es decir, presentarles asuntos sintéticos, motivos que susciten la aplicación del mayor número de facultades, en cada caso, y los estimulen por el placer, dando rienda suelta á su actividad. Pero ya los conocimientos organizados por la abstracción, esto es, ya la instrucción debe dejarse para cuando el niño tiene mayor estructura cerebral, después de los siete años. Y no debe olvidarse, ya sea que se trate de ejercicios educativos, es decir, de la gimnasia de las facultades, mediante objetos ó fenómenos presentes, ó bien después de la edad señalada como punto de partida para la instrucción de retener nociones abstractas cada vez más generales, no se debe perder de vista, repito, que las lecciones no deben ser muy largas y que el principio del cansancio mental debe ser el indicante para terminar el trabajo. En las labores escolares es indispensable pasar de un conocimiento á otro; pues bien, este mismo hecho constituye un descanso, siempre que tanto uno como otro trabajo sean limitados y suficientemente diversos entre sí, pues es claro que entonces las facultades que toman parte principal en uno, no la tomarán en el otro. La memoria, facultad preciosísima, y que es en alto grado valiosa cuando nos limitamos á que solo desempeñe en la actividad mental su magnífico papel, puede llegar á ser nociva para el regular funcionamiento de la inteligencia, si queremos que, á toda costa, todo se aprenda de memoria, entiéndase ó no; pero semejante cosa debe desecharse por el notorio perjuicio que acarrea al saludable ejercicio de las otras facultades, que casi deja en la inacción.

Mas dándole forma preceptiva á los conceptos anteriores, diremos: (1) Deben cuidarse higiénicamente las funciones de nutrición y las facultades de relación. (2) Se debe dormir en el mayor reposo, más en la infancia que en la edad adulta. (3) No debe principiarse la enseñanza instructiva antes de los siete años. (4) Al principio de la enseñanza deben predominar los ejercicios educativos, elementales, pero variados; y siempre en el estudio debe irse de lo concreto á lo abstracto y especializando lentamente. (5) Debe irse en todo aprendizaje de lo particular á lo general, de lo conocido á lo desconocido y de lo independiente á lo dependiente. (6) La duración del estudio, en cada caso, no debe ir más allá del instante en que se inicie cansancio mental. (7) Durante el trabajo intelectual se debe variar el asunto del estudio y deben ir seguidos los más disímolos. (8) Solo debe encargarse á la memoria lo que haya sido comprendido por la inteligencia. Tal es en breve síntesis lo principal que atañe á la higiene del cerebro y á la pedagogía de la inteligencia.

## METHODS OF MEDICAL EDUCATION.

By VICTOR C. VAUGHAN, Ph. D., M. D.,

*Dean of the Department of Medicine and Surgery in Michigan University.*

I will suppose that we require of our students on admission to the medical school not less than is required of those who enter the scientific department of our best universities. Certainly our requirements for admission should not be less than this. Our students have had fair training in English, at least one year in Latin (though two would be better), a reading knowledge of German or French, or both, have been well drilled in mathematics through arithmetic, elementary

algebra, and plane geometry, are fairly well posted in general and national history, and have received fair instruction in the elements of physics, botany, zoölogy, and physiology. I state that I will assume that our medical students have had the above-mentioned training. Our best high schools do this work, and do it fairly well. I wish to state here, parenthetically, that an experience of more than fifteen years has convinced me that the average graduate of our best high schools does his medical work quite as satisfactorily and intelligently as the average graduate of a classical course in college; while the man who has taken a scientific course in one of our best universities has an advantage over both of the others. For one, I shall be opposed to requiring of our matriculates the possession of a bachelor of arts or a bachelor of laws degree until the courses leading to these degrees in our colleges have undergone some radical changes. With such requirements and with a medical course covering four years of nine months each devoted to instruction, what shall we teach and how shall we teach? The first part of this question is easily answered. There are certain sciences from which medicine draws all its resources. Without these sciences there would be no medicine, as we teach and practice it. These sciences are physics, chemistry, botany, anatomy, physiological chemistry, histology, bacteriology, and hygiene. Our student has had, before admission, a fair drill in physics, and it will only be necessary to develop certain branches of this very broad subject. One semester of lectures, accompanied by demonstrations and strengthened by text-book recitations on heat, light, sound, and electricity, is at present quite necessary, and would remain so were all our students bachelors of art. The student will get additional information on many of these points in other courses. Heat and light must be discussed in the course in hygiene. Refraction will be dwelt upon in the demonstration course in ophthalmology. Electricity will be investigated in the laboratory of electro-therapeutics. It would be well if general and analytical chemistry could be required for admission to the medical school, but unfortunately the instruction given in this science in many of our colleges is so inadequate, and in some instances so erroneous, that the student who has had no instruction has an advantage over the one who has for years memorized formulas and written equations. Even in our scientific schools the study of chemistry has been narrowed down to methods of analysis. Lectures and text-book work are essential, but they should never become the chief reliance in the study of chemistry. The student should be supplied with adequate laboratory facilities, then given a chemical substance, and be requested to ascertain experimentally all he can concerning its solubilities, incompatibilities, and decompositions. This experimental study should be supplemented by properly directed reading. Analytical tables and schedules should not be placed too early in the hands of a student. They make of him a mere manipulator of test-tube reactions, which he produces but fails to understand.

In nearly all of our medical schools anatomy is taught, not as a broad and important science, but simply for the service which it may render the physician and surgeon in their work. The embryological development of the various anatomical structures is not considered. Time is spent in memorizing the names of the smallest muscles, blood vessels, and nerves, and the great wealth of knowledge which would be opened up to the student by even a short study of comparative embryology and anatomy is wholly lost. The effect of this method of teaching anatomy tells upon those who give instruction in this branch as well as upon those who listen. The professorship of anatomy is made a stepping-stone to that of surgery, and one can easily see why the number of scientific anatomists, those who conduct valuable researches in this branch, are so few in this country. The study of anatomy too frequently means simply a study of osteology and myology, with a glance at the blood vessels and nerves. The idea that one can understand

the complicated morphology of the central nervous system of man with the superficial and careless attention given to it by the average medical student is absurd. Visceral anatomy is another part of this broad subject to which insufficient attention is given. On the other hand, if the student has had good training in general biology and has dissected different types of animal life, beginning with some of the lowest and least complicated in structure, anatomy becomes a most deeply interesting subject. He now sees the plan of development. Please understand that I do not suppose that any extensive course in general biology or comparative anatomy could be or should be included in a four-years medical course, but this work should be embraced in the preliminary training. Those of us who may have influence in shaping the lines of study offered in the courses preparatory to medicine by our scientific schools and universities should bear this in mind, and if these schools fail to provide proper instruction in this and other branches, we must lengthen our terms of medical study to six or seven years and give such instruction.

The teaching of bacteriology simply by lectures or recitations without practical laboratory work is a farce. Some time ago I received a letter from a professor of bacteriology in one of the prominent medical schools in one of our large cities, asking me to send him some cultures of pathogenic bacteria. I replied that if he would send me agar tubes I would inoculate the same and return them to him. He then wrote me asking what agar is and how such tubes should be prepared. That certain bacteria bear a specific causal relation to certain diseases has been demonstrated beyond all peradventure, and yet hundreds of medical students are given their degrees and thus licensed to treat these diseases without being taught the methods of detecting and isolating the germs. The lecturer tells his students that the Löffler bacillus is the cause of diphtheria and that in many instances the recognition of this bacillus is the only method by which a correct diagnosis can be reached, and yet the student is not instructed in the technique necessary to make this diagnosis, and he goes forth practically ignorant and helpless on this point. This is not just to the student. Practical, thorough laboratory instruction in bacteriology must not only be offered to, but must be required of, every medical student. Is it any wonder that one of our leading medical journals has lately complained that the whole field of preventive medicine is likely to be divorced from medicine? The trouble is that medical education has not kept abreast of the recent discoveries in science. The medical man properly instructed should be the best equipped sanitarian, and yet I have more than once heard an intelligent layman trying to convince an ignorant doctor that the so-called germ theory is no longer a mere theory, but is founded upon demonstrated facts. If medicine is to hold its position among the learned professions our medical schools must teach bacteriology, not only by lectures, but by weeks of thorough drill of each student in the bacteriological laboratory. What is true of bacteriology is also true of the broader subject of hygiene, of which the former is but a part. In talking with a prominent physician in London a few years ago I expressed a desire to meet one of the most eminent sanitarians of that city. "Oh," said my friend, "he is not a doctor, he is only a sanitary crank." Will the profession thus throw aside its most worthy possessions? Is not the man who prevents disease worthy to be ranked with him who treats typhoid fever or amputates a crushed limb? Are we to say that the Jenners, Pasteurs, Pettenkofers, and Kochs do not belong to us? Yet there are many architects and engineers who know more about the principles of ventilation, water purification, and sewage disposal than the average doctor does. It is for us who are engaged in the teaching of medicine to determine whether or not the profession of medicine shall possess the rich fields of preventive medicine. Shall we turn this work over to others? This certainly must not be done. Why should not the sanitarian who studies the chemistry and bacteriology

of drinking water and the adulterations and putrefactive changes in food be a specialist in medicine as well as the ophthalmologist or the laryngologist? Certainly the medical man who has had broad training is better fitted to do work in preventive medicine than he who knows nothing of disease. The answer to this question will depend upon the facilities which our medical schools offer for instruction in these branches. I hope to see the time when the possession of a degree in medicine will indicate that the possessor has had a broad, scientific training. It is universally admitted that anatomy can not be taught without practical work in the dissecting room, but instruction in physiology is generally given exclusively by lectures, class-room demonstrations, and text-books. Nevertheless it is certainly true that the medical practitioner needs to recall his physiological knowledge quite as frequently as he does his anatomical learning. Indeed, functional disturbances constitute probably four-fifths of the cases which come under treatment. It is quite as important for the physician to know something of the innervation of the heart as it is for him to understand the arrangement of the valves. Laboratory instruction in physiology is desirable, and in physiological chemistry it is absolutely essential. Of course histology and the microscopical study of diseased tissue can be taught only in properly equipped laboratories, and gross pathology in the dead room. Laboratory methods are now carried into clinical teaching by a few of our best medical schools. This, in my opinion, is one of the most important advances which has been made in recent years in the methods of medical instruction. From two to four hours per day for from four to six weeks are employed by the junior student in the surgical laboratory, where he makes amputations, ligates blood vessels, and resects the intestines in living animals, giving all the attention to narcosis, asepsis, and dressing which would be bestowed upon similar operations in man. The class in methods of medical diagnosis must now, in addition to the drill in auscultation and percussion, make chemical and bacteriological examinations of urine, blood, vomited matter, and sputa, the hospital containing a room supplied with the facilities necessary for this work. Demonstrations in obstetrics, ophthalmology, and laryngology are given on manikins. Methods of detecting and correcting errors of refraction are taught to each student. The ophthalmoscope, laryngoscope, and other instrumental aids to diagnosis are employed by the student under the direction of a competent instructor. The student now gets all of these demonstrative courses before or simultaneously with his clinical instruction in the amphitheater, at the bedside, or in the outdoor dispensary. The methods of medical education might be grouped in the following manner: (1) Lectures; (2) recitations from text-books; (3) laboratory instruction; (4) amphitheater clinics; (5) bedside teaching. All of these methods must be employed to some extent. Lectures upon many subjects can not be wholly replaced by text-book instruction. A subject to which new and important contributions are being constantly made can not be fairly presented exclusively by a text-book, however accurate such a book may have been when it was written. It certainly is better to use a book a year behind the times than to listen to a lecturer twenty years behind the times, as some of us probably did during our medical course. Laboratory methods, as I have already stated, are growing in favor, and their application will find a yet wider range. Spectacular clinical teaching, in which the operator or the lecturer is the center of interest, is a theory of the past. Ward and bedside teaching, with all the laboratory and instrumental aids to diagnosis, afford the greatest instruction to the student. Certainly medicine grows constantly more scientific and this growth will continue until our best medical schools will offer better facilities for broad scientific culture than can be found elsewhere.

THE MEDICAL HISTORY OF CHRISTOPHER COLUMBUS, AND THE PART TAKEN BY THE MEDICAL PROFESSION IN THE DISCOVERY OF AMERICA.<sup>1</sup>

By A. M. FERNANDEZ DE YBARRA, M. D., of New York.

*Amicus Plato, sed magis amica veritas.*—ARISTOTLE.

One of the most important events in the history of humanity, and perhaps second only to the birth of Christ in beneficial results, is, without any species of doubt, the discovery of America by the Spaniards under the leadership of Christopher Columbus. Willing and unwilling visitors certainly did come from the Old World to the New a number of times before that date. In the fifth century of the Christian era a few Buddhist missionary priests came, either directly from China to a country which they called Fusang, and known to us now as Mexico, or they first, and most probably, settled in Japan and afterwards crossed from there to the Pacific coast of America; the voyages of the Northmen in the tenth and eleventh centuries, the traditional narratives of which tell us of the deeds of the daring sailor, Eric the Red, and the discovery of Helluland, Markland, and Vinland by his famous son, Lief Ericsson. The story of the Venetian brothers, Nicolo and Antonio Zeno, the first wrecked in 1390 upon one of the Faroe Islands, his subsequent visit to Greenland and return, and the second embarking on an unsuccessful voyage of discovery in the Atlantic Ocean, about the year 1400, to verify some fishermen's reports of the existence of land a thousand miles or more to the west from the Faroe Islands. The old and often-repeated rumors concerning the fancied Island of St. Brandan, which several Portuguese and Spanish captains imagined they had beheld beyond Madeira. The seemingly truthful statement in regard to the Spanish pilot, Alonzo Sanchez de Huelva, who, sailing in 1484 (which should be 1474), "one year more or less," from the Canaries to Madeira, had been tempest-tossed by violent easterly winds upon an unknown island (the Island of Hispaniola or San Domingo), where he landed, took an altitude, and wrote an account of all he saw and all that had occurred on the voyage. He succeeded in returning, arrived at Terceira (one of the Azores) sick and worn out, and soon after died, leaving Columbus, who had hospitably received him in his house and nursed him, heir to his papers.

All these, and more, pre-Columbian voyages, legendary reports, and fanciful descriptions of America are completely divested of true historical importance, and did not contribute a mite to our geographical knowledge or to the betterment of mankind. To speak of them as implying, in any sense whatsoever, that they constitute a discovery of America is perfectly absurd. To expatiate about them with the mental reservation of robbing Columbus of his well-earned title of discoverer of the New World is the height of folly. In 1492 the American continent was to a certain degree as unknown to the rest of the world as the nebulous inhabitants of the planet Mars are to us to-day.

On the present four hundredth anniversary of that paramount event in history almost all classes and conditions of men have endeavored to bring forth their representatives who, in some way or another, had anything to do with it. Mariners are still singing the wonderful skill and intrepidity of their seafaring companions of the fifteenth and sixteenth centuries. The military have spoken of their famous captains, and with minute details referred to their heroic feats and glorious conquests, not always wise or even right. The clergy have told us of the first American bishops, large numbers of pious and lion-hearted missionaries, and the numberless martyrs sacrificed in our luxuriant forests. Politicians have pointed out the

<sup>1</sup> This paper was received too late for insertion in the proper section.

many examples of good, indifferent, bad, and very bad rulers, together with chieftains and leaders totally destitute of diplomatic tact. Lawyers have shown who were at that time eminent legislators, and put on record the notable judicial contests arising in consequence of the discovery of America. Physicians only have remained silent in this universal revival, when we, as a class, contributed very largely to the realization of the constant dream of a great genius, thought then by almost everyone but a distinguished Italian physician and a modest Spanish village doctor to be merely a madman.

If modern anthropological science can justly boast of having made clear the intimate relations existing between the shape, volume, and minute structure of the internal organs of man and his outward manifestations, both physical and psychical, it is evident that in speaking of such a profoundly important historical figure as Christopher Columbus, an humble attempt to examine his personal appearance, temperament, physical ailments, and the cause of his untimely death may greatly help to a more accurate appreciation of his mental characteristics and moral nature.

First, as to the date of his birth. This is a *vexata questio* which it would be out of my power in the limits of this short paper to discuss. Washington Irving, relying upon the evidence of Andrés Bernáldez, a historiographer and intimate friend of Columbus, states it to be about 1435 or 1436. Don Fernando, the admiral's second son and his most faithful biographer, relates that in a letter written by his father to the King and Queen of Spain, dated 1501, he declares that he had then been forty years at sea, and in another letter that he was 14 years old when he first went to sea; so that allowing a year either way for probable inattention to circumstantial details, we get the date of his birth, fixed by his own hand, at about 1447. If we take into consideration that he did not go to sea during his seven years of patient waiting in Spain—from 1485, when for the second time he entered that country from Portugal, to 1492, when he set sail westward on the Sea of Darkness—we must then acknowledge that in referring in 1501 to his being forty years at sea, he did not probably reckon the time spent in surmounting the difficulties encountered at the court of Ferdinand and Isabella. This would bring us to 1440 as the date of his birth; but if we make a calm and philosophical analysis of the expression, "being forty years at sea," from a sailor who had the year before arrived, a prisoner, in fetters, poor, sickly, and dejected, from his third voyage across an unknown ocean, and bearing in mind his former unequivocal statement that he had "followed the sea for twenty-three years without being on shore any space of time worth accounting," in which period he had been to and from upon the Mediterranean, the Grecian Archipelago, France, Flanders, the coast of Guinea, the Canary Islands, Madeira, Porto Santo, the Azores, Cape Verde Islands, England, Ireland, Iceland, and sailed a hundred leagues beyond this "Ultima Thule" of Ptolemy, we will be forced to admit that that phrase only means a sailor of forty years' experience, the same as any old professor, architect, lawyer, or physician might express himself in like circumstances, regardless of the few years spent in traveling, sickness, or some temporary occupation. The place of his birth was the city of Genoa.

From the accounts of his personal appearance given by his son Fernando, Las Casas, Andrés Bernáldez, Pietro Martire d'Anghiera, the Portuguese historian João de Barros, Agostino Giustiniani, Antonio Gallo, and others who knew him well, I gather that Columbus was a man of commanding presence, tall and well built, with fair, ruddy complexion somewhat freckled, oval face with rather prominent cheek bones, broad and high forehead, medium-size mouth, aquiline nose, grayish-blue eyes, very light reddish hair, and beard prematurely turned gray. He was of a genial disposition, courteous and graceful, his conversation agreeable and interesting to such a point that strangers were quickly attracted and felt at ease. An

indefinable air of dignified command surrounded him, and the magnetism of his noble soul was perceptible in the tender glance of his glowing eyes when his religious enthusiasm was kindled by the divine spark of genius that abided in him. Of a great nervous susceptibility, his mind was highly imaginative and poetical. Naturally religious, he was temperate in eating and drinking and puritanical in his habits.

My search for particulars regarding the life of Columbus prior to his arrival in Portugal was far from satisfactory. From the period of his first going to sea, which was about 1460, until the year some biographers say his vessel was burned, near the Portuguese coast not far from the city of Lisbon, nowhere in history have I met with a distinct mention of his name. We have positive evidence, however, that in 1472 he was in the city of Savona, Italy, from the fact of his signature being appended as witness to the will of one Nicolo Monleone, under date of March 20 of that year. It appears very probable that in 1469 he took part, under the command of a French vice-admiral of the name of Caseneuve, in a successful sea fight to capture several Dutch ships returning from the herring fishery in the Baltic. We find him afterward in a terrible naval engagement between Lisbon and Cape St. Vincent, trying to get possession of four richly laden Venetian galleys on their return from Flanders, the desperate struggle lasting from morning till evening. The hand grenades and other burning missiles used in the battle caused at last a general conflagration among the vessels, which having been lashed together with iron grapplings, could not be separated, and the crews were compelled to leap into the water to escape the fire. Columbus's son, Fernando, goes on to say that "his father, who was a good swimmer, finding himself at the distance of 2 leagues from land, seized an oar, and by its aid succeeded in reaching the shore." It was close at hand to Lisbon, where he went and there made his abode. This happened in the year 1470 or 1471, and in 1473 he married the Portuguese lady, Philippa Moniz de Perestrelo, and went to live with her at Porto Santo, a small island on the Atlantic Ocean, 25 miles northeast of Madeira. There his son Diego was born in 1474.

The subject of the medical history of Columbus is a barren one, so barren indeed that it has never before been touched upon. I asked the present Duke of Veragua, and such living sterling biographers of the illustrious Genoese navigator as Mr. Henry Harrisse, Mr. José M. Asensio y Toledo, Profs. John Fiske and C. K. Adams, Mr. Justin Winsor, and Mr. Cesareo Fernandez Duro, and they all answered me that they did not know of anybody who had investigated the medical aspect of the life of Columbus. I consulted the librarians of the Smithsonian Institute at Washington, Lenox and Astor libraries of New York, and the Public Library of the city of Boston; I searched carefully all the old standard historical authorities, but little did I find, and here it is embodied. I must, however, acknowledge my indebtedness to a recent monograph of Dr. Calatraveno, of Madrid, Spain, for many things I say in this paper about the part taken by the medical profession in the discovery of America. Nearly a year of constant inquiry and exploration in this unproductive field has resulted in what I venture to call my contribution to this first Columbian Pan-American assemblage of scientific men.

The piratical character of the seafaring life of Columbus's time, and the peculiar construction of the vessels, necessarily exposed its followers to unceasing hardships, privations, and many unavoidable dangers to health. The severity of this early manner of living in a man of such well-marked sanguine temperament as that of the immortal sailor, must have very insidiously tended to undermine his naturally strong constitution, after "being at sea twenty-three years, without remaining on shore any space of time worth accounting," and render him liable at the age of 46 years to the ailments and sicknesses which he subsequently

suffered during his four voyages of discovery to America, to which must be added the grief, disappointment, mental anxiety, and moral depression he endured, all together combining in the production of the chronic disease that put an end to his imperishable career at a comparatively premature period of life. Regarding hereditary predisposition to disease, I may safely say he had none. His father died at an extreme old age (in 1496 or 1498) and his mother a few years before. He was the eldest of five children, four boys and a girl, and not one of the others showed hereditary taint. His parents belonged to the healthy, sound, hearty, and frugal types of the Ligurian peasantry.

On Friday, August 3, 1492, Columbus sailed westward from the little seaport of Palos de Moguer, Spain, to plow the sea of darkness in quest of a new world. On Friday, October 12, of the same year, he discovered America, and also on Friday, March 15, 1493, he dropped anchor, back from his mission, at the same little harbor of Palos. He spent two hundred and twenty-five days in this first round trip to the Western Hemisphere, in which time I have found no record whatever of his having suffered any sickness, except casual references to "sore eyes." This slight and transitory ocular affection, which he often experienced afterwards, I consider to have been probably due to blepharitis or styes or to granular ophthalmia, brought on by straining the eyes in search of land in a diaphanous atmosphere where the rays of light are most intense. Perhaps the admiral's leaning toward albinism also contributed to it. His excellent eyesight at night seems to lend weight to this opinion of mine.

He undoubtedly suffered great anxiety, tribulation, and mental anguish when the crews began to murmur and finally became openly impatient and mutinous at not finding land; but this prejudicial moral effect on his health must have been entirely extinguished by the joy, satisfaction, and pride of having succeeded in his stupendous enterprise. The two shabby tricks of Martin Alonso Pinzon, captain of the caravel *Pinta*—by far the best sailer of the three—when on the 20th of November, sailing along the coast of beautiful Cuba, he treacherously deserted his chief, and on the 12th of February he surreptitiously abandoned him again to bring the news of the discovery home first, must have also caused Columbus no little pain and dejection.

He put to sea again on his second voyage of discovery, from Cadiz, September 25, 1493, this time with a fleet of three galleons or carracks and fourteen caravels, carrying 1,500 people on board, instead of the 120 who accompanied him in his former unparalleled hazardous cruise.

This large number of men, among whom were many aristocratic young fellows, daring, supercilious, irascible, and obstinate hidalgos, left without occupation at the end of the war with the Moors, were placed under the medical care of Dr. Diego Alvarez Chanca, a distinguished practitioner of great reputation in the city of Seville, who was also physician in ordinary to the King and Queen of Spain, and had attended their firstborn, Princess Isabella (who afterwards became Queen of Portugal), during her serious illness the year before. Speaking of him in a memorial addressed to Ferdinand and Isabella, dated January 30, 1494, Columbus wrote:

You will inform their Highnesses of the continual labor that Dr. Chanca has undergone, from the prodigious number of sick and the scarcity of provisions; and that, in spite of all this, he exhibits the greatest zeal and benevolence in everything that relates to his profession. As their Highnesses have intrusted me with the charge of fixing the salary that is to be paid to him while out here (although it is certain that he neither receives nor can receive anything from any one, and does not receive anything from his position equal to what he did receive and could still get if he were in Spain, where he lived peaceably and at ease, in a very different style from what he does here), I have, nevertheless, not ventured to place to the credit of his account more than 50,000 maravedis (about \$725) per annum, as the sum which he is to receive for yearly labor during the time of his stay in this country.

The letter or report of this learned and magnanimous man to the Chapter of Seville, from which I quote two passages further on, is the first scientific monograph written about America, and worthy of careful perusal.

On the 27th of November the fleet arrived in the harbor of La Navidad, in the island of San Domingo, and found the little fortress completely destroyed, and each and every one of the 38 men left there on the first voyage had been massacred by the native Indians. Columbus caused to be built a neat little town, to which the name of Isabella was given, and remained in this island until April 24, 1494, when he put to sea again and discovered Jamaica, May 3, and visited Cuba for the third time; returning from there, he passed by all the southern coast of Jamaica and Hispaniola and discovered the little islands of Beata, Saona, and Mona.

The day after leaving this last island, in the passage between San Domingo and Porto Rico, September 25, 1494, worn out with the toil and hardships of a five-months cruise among people who, though very kind and generous, could not afford him the relief and comfort he so much needed, and in which time his incessant watching, nervous excitement, and high hopes of finding large quantities of gold and spices had sustained him wonderfully, the inevitable reaction at last overtook him, and his whole system suddenly collapsed. "He lay in a stupor, knowing little, remembering nothing, his eyes dim and vitality oözing, until the little fleet sorrowfully, but gladly, entered the harbor of Isabella." Columbus himself acknowledges that for thirty-three days he had slept next to nothing, when he began to feel very tired and fell into a lethargic state which almost deprived him of his life. He remained sick very nearly five months, under the care of Dr. Chanca.

In the early part of April of that year he had been seized with intermittent fever at Isabella, where the same principles of heat, humidity, porosity of the soil, and presence of decaying vegetable matter, which gave an extraordinary fecundity to the uncultivated fields, worked havoc among the Spaniards. Many of them are also said to have suffered at La Vega under the torments of a disease called "the scourge" (syphilis?), the origin of which, whether American or European or Asiatic, has been a subject of great dispute for over three centuries. Dr. Chanca, in his letter to the Chapter of Seville, expresses himself on the situation thus: "One-third of our people have fallen sick within the last four or five days, which I think has principally arisen from the toil and privations of the journey, and another cause has been the variableness of the climate." In another place he says: "The admiral had at one time determined to leave the search for the mines until he had first dispatched the ships, which were to return to Spain, on account of the great sickness which had prevailed among the men." Does he refer here to venereal diseases? I incline to the affirmative, but in the sense of gonorrhoeal and not syphilitic diseases. Concerning his first statement, that one-third of the colonists had fallen sick in four or five days, I firmly believe it was due to the bad quality of the provisions brought from Spain, and to malarial infection, not very well understood in those days. The miraculous *pulvis febrifugus orbis Americani* was not yet known to Europeans. The existence and wonderful virtue of "quinaquina," which later on saved the life of Charles II of England, Louis XIV of France, and Frederick the Great, were then only known to the native inhabitants of undiscovered Peru.

What was that dangerous disease from which Columbus did not entirely recover for nearly five months? Was it a disease of the nervous system? The only affections of that kind most likely to have developed are acute softening of the brain or idiopathic meningitis. But acute softening occurs always in very old persons, is apt to be preceded by mental confusion, a feeling of numbness, and some slight impairment of motion; and in idiopathic meningitis there are from the beginning

an intense headache, vertigo, nausea, and vomiting. These two diseases also run their courses generally in a short time, the usual termination in acute meningitis being death; cerebral softening always leaves behind permanent disorder of the mental, sensory, or motor functions.

Could it have been scurvy? Decidedly no, because, although scorbutus was in those days a very familiar disease among soldiers and sailors, arising from a deficiency of fresh meat or vegetable diet, and sometimes to be found also in badly ventilated, dark, and damp prisons, owing to the want of proper assimilation of food, neither insomnia, stupor, nor delirium form a part of the onset of this disease. Besides, scurvy is so slow and gradual in its development that the patients do not know when it begins.

In the absence of a clinical history of the case, let us scrutinize a little more the simple historical account of the disease. In going from Mona to Porto Rico, Columbus's fatigue and weakness and want of proper food "cast him into a dangerous disease between a pestilential fever and lethargy, which deprived him of his sense and memory." This is his own way of expressing his malady. It certainly was, then, one of the following three low-type fevers—typhus, typhoid, or relapsing.

We must not lose sight of the fact that he had just got over a protracted attack of paludal poisoning, which consequently left him in an anæmic and debilitated condition at the time of embarking in this five-months cruise, thus offering an inviting soil for the favorable incubation of a specific, blood-disorganizing fever such as the above-named ones.

Not knowing the exact bodily temperature, nor the characteristics of its daily variations (and for the best of reasons—the clinical thermometer had not yet been invented), nothing whatever in regard to the peculiarities of the pulse, the actual condition of the skin, the tongue, the bowels, the presence or absence of eruption, epistaxis, lung symptoms, nausea, or vomiting, the anomalies of the urinary excretion, etc., we can not make a good differential diagnosis between those three low specific fevers. As a rule, we find in all of them the same symptoms of general malaise, weakness, drowsiness, at the beginning of the disease; but my opinion is, however, that it was typhus, because of the prolonged convalescence, which must have been due to some pulmonary complication, partial paralysis, scurvy, dysentery, suppurative inflammation of parotid, submaxillary, or inguinal glands, or more probably of the joints. There is another important circumstance which leads me to make the diagnosis of ship fever, and that is that Columbus, as a general rule, very seldom went ashore, but remained on board while waiting at the different harbors, coves, anchorages, and roadsteads, thus necessarily exposing himself more to the infection than the average of his companions, whose nervous systems could not have been in such an unstrung and depressed state as his.

When Columbus recovered consciousness at Isabella he found his dear brother Bartholomew, whom he had not seen for six years, seated by his bedside and tenderly nursing him. This happened on the 8th or 9th of October, which shows that the stupor lasted during the first two weeks of the disease—another diagnostic symptom in favor of typhus.

Early in March, 1496, the immortal navigator sailed for Spain; but he did not arrive there until June 11, having exhausted all his provisions, and the famine was such that the crews came near eating up some of the thirty or more Indian captives whom they were taking to Spain. The haggard and starving party dropped anchor in the same harbor of Cadiz from which many of them had joyously set sail with Columbus two years, eight months, and sixteen days previously.

Columbus started on his third voyage of discovery with a fleet of six ships, carrying about 200 men besides the sailors, from the little seaport of San Lucar de Barrameda, on May 30, 1498. On June 21, at the island of Ferro (the most west-

erly of the Canaries), the admiral divided his fleet, sending three ships directly to Hispaniola, while with the other three he steered southwest. Prosecuting his voyage toward the Cape Verde Islands, in the last days of June, and "as he advanced within the tropics, the change of climate and the close and sultry weather brought on a severe attack of the gout, followed by a violent fever," says Washington Irving. On the 31st of July he discovered the island of Trinidad, and caught a glimpse of terra firma at the delta of the Orinoco River; coming out from it through the passage which he named Dragon's Mouth (Boca del Dragon), during the second week of August, "he suffered a great deal from gout and ophthalmia," says Navarrete.

These two are the first distinct and positive historical references to Columbus suffering from gout. As for the the transitory ophthalmia, I have already stated my opinion about it, only adding that it is a frequent complication of rheumatism, but not of gout. Now I shall endeavor to prove that Christopher Columbus was never afflicted with gout, which is contrary to the firm belief of all accepted standard non-professional authorities.

Gout is more decidedly hereditary than rheumatism, and occurs in those who live high or drink large quantities of malt liquor, or is seen in persons whose systems have been impregnated with lead. The greatest maritime genius of the fifteenth century was of too humble birth to have inherited the gouty diathesis, and too frugal in his habits to have acquired a malady the result of overindulgence in the pleasures of the table, especially when cruising with very scanty provisions; surely there could not have been much lead in his system. Gout is characterized by the occurrence of paroxysms of severe pain in a small joint—the great toe usually. Gout in the foot is called podagra; gout in the hand, chiragra; and gout in the knee gonagra. But Columbus suffered pain in several joints, of the upper as well as the lower extremities, his movement was slow, rigid, and jerking, so that it was accomplished with difficulty, and his disorder, therefore, could not very well be placed under any of these three Latin divisions of gout.

There are yet two very important diagnostic factors against the theory of gout, viz., the season of the year in which exists the greatest tendency to the occurrence of the seizures (winter), these two first attacks taking place in the middle of the summer and, moreover, that we meet in the course of the distemper with no cardiac complication, at least no valvular affection, as so constantly happens in rheumatism, and which sequel was the ultimate result of the disease that launched Columbus into eternity; and, furthermore, in complete possession of all his mental faculties, which does not occur in gout where the morbid changes induced in the kidneys give rise to cerebral symptoms at the time of death.

The admiral arrived at Isabella on the 30th of August and was immediately put in irons and thrown into prison by Bobadilla, who had come from Spain a week before. While confined in prison and deprived of intercourse with anyone, loaded with fetters and chains in the fort of the little town, he was sick for several days, probably with intermittent fever or rheumatic pains, improperly called gout. He was put on board a vessel and sent to Spain early in October, 1500, arriving at Cadiz on a December day, and as he passed, his stately and venerable figure burdened with shackles and chains, through the streets of that city he awakened a great popular outburst of sympathy for him and indignation at his persecutors, which reproof immediately reëchoed in the wealthy cities of Seville and Granada.

Fortunately the passage had been calm and fair and of but moderate duration, rendered also less disagreeable by the kind treatment of Alonzo de Villejo, to whom he was given in custody.

While on board the ship he had written a long and eloquent letter, full of pathos, to Doña Juana de la Torre, the nurse (*ama*) of Prince Juan, a lady high in favor with Queen Isabella, to whom her brother Antonio, a fellow-voyager of Colum-

bus, straightway carried the epistle on landing. In studying the ideas and wording of this remarkable letter, I find that his reason was just beginning to lose equipoise under the strain of the great humiliation he was then enduring and the disordered condition in which his unexpected, unwarranted, and unworthy arrest had thrown all his private affairs. This clouded state of his intellect suffered a more aggravated relapse on two or three other occasions, when in moments of despair and heartrending anguish his religious enthusiasm completely overpowered his understanding, and of which I will speak later on.

During the seventeen months elapsing between his arrival from the third voyage and his departure again on the fourth not a word, that I know of, is said in history about Columbus being afflicted with gout, which is a strong argument against the theory of his suffering from that malady. When much better fed, in company of cavaliers and rich men, he should have had more paroxysms of that "eminently respectable disease," as Sydenham used to call it, than when living as a sailor on strange seas, short of the most necessary provisions.

The equipment of the fleet on the fourth and last voyage consisted of four small caravels, with crews numbering, all told, 150 men. Columbus's brother Bartholomew, and his younger son, Fernando, then a boy of 14, accompanied him. They sailed from Cadiz on the 11th of May, 1502, and on the 7th of November, 1504, after a tempestuous voyage and narrow escape from shipwreck, he landed back at San Lucar de Barrameda, so sick and thoroughly worn out that he could not personally go to court to give an account of his new discoveries, but had to send in his place his youthful son, Fernando.

While sailing along the coast of Honduras, in the middle of August, 1502, there was an incessant tempest, with heavy rains and such thundering and lightning that "it seemed as if the end of the world was at hand." The vessels had been so violently tossed about that their seams opened, and the provisions were damaged by the rain and by the leakage. During a great part of this time Columbus "suffered extremely from the gout, aggravated by his watchfulness and anxiety." His illness did not prevent him, however, from attending to his duties; he had a small cabin constructed on the stern of his vessel, from which, even when lying down on his bed, he could keep a lookout and direct the course of the ships. Columbus himself says that many times he was so ill that he thought his end approaching.

The little fleet at last succeeded in passing the Cape Gracias á Dios, on September 14, after struggling with the wind and the waves and the currents for about forty days. When on the coast of Veragua (Republic of Costa Rica), in the middle of October, many days of constant mental disturbance and nights of sleepless anxiety preyed upon a constitution undermined by a slow blood poison, by grief and disappointment, by hardships, by unhygienic surroundings, and by want of proper treatment, finally producing an illusory vision, deemed by Columbus in his religious conceit of private revelation to be really God-sent and supernatural. In a letter to the sovereigns of Spain he gives a very solemn account of this hallucination, in which he heard in the course of a vivid dream a piteous voice reminding him of Scriptural passages to comfort him and encourage him to trust in the Almighty. Such psychical perturbation can easily be explained if we take into consideration Columbus' highly imaginative cerebration, his exalted religious conceptions, his daily devotional exercises, and his deeprooted belief that he was the chosen one from among men to carry the light of the true faith into far distant, unenlightened, and pagan lands. This favorable field, when well plowed by a chronic and painful disease and harrowed by the iron teeth of grief, could without difficulty produce a momentary phomania. Like the firm trust of all impassioned religious or political reformers, his sublime reliance in his lofty predestination certainly served him to overcome the multitude of obstacles he found in his path. And here we find the proof once more of the undiscernible and undefinable boundary between insanity and genius. While visiting Jamaica in the latter

part of June, 1503, in which island he was obliged to spend a year, Columbus suffered another attack of the so-called gout, and malarial fever of long duration, on the shores of the harbor of Santa Gloria, known to-day as St. Anne's Bay, which rendered him a cripple.

During all this fourth voyage his mental and physical condition was very much weakened, though hope, to be sure, had not altogether departed from his ardent and sanguine nature; but it was a hope that had experienced many reverses, and its pinions were sorely clipped. His voyages of discovery always involved hardships enough to wear out the strongest human frame, having to navigate among unforeseen dangers, without chart or pilot or previous knowledge of the countries, their inhabitants or language; to keep a constant and anxious watch at all hours, in all kinds of weather, subject to the caprices of the wind and without proper food. Age was already rapidly making itself felt when Columbus undertook this his last and most disastrous cruise (55 years old), the ultimate ten years of which were filled with care, physical ailments, and troubles of many sorts. For several weeks before he landed back at San Lucar de Barrameda his tiny ship was thrown hither and thither in mid-ocean by violent winds and hill-like waves, combined with tropical showers. All that time Columbus was suffering the most excruciating pains from his old malady, until his crazy and shattered little bark anchored in the harbor, with her haggard, emaciated, crippled, and almost blind master aboard. From San Lucar he had himself conveyed to Seville, where he hoped to enjoy the much-needed rest of mind and body and to recruit his health; but fortune continued to frown upon him, for he ascertained on arriving at that city that all his private affairs were in a state of confusion and entanglement. Since he had been sent to Spain from San Domingo, shackled like the vilest of culprits, when his house and effects had been seized and confiscated by order of Bobadilla, his rents and dues had been unlawfully retained in the possession of Governor Ovando, the successor of Bobadilla in command of the island. He was therefore in actual penury. He remained at Seville during the rest of that winter and part of the following spring, a victim of his chronic and painful illness.

At the beginning of May, 1505, feeling a little better, he went with his brother Bartholomew to court, then sojourning at Segovia, to personally plead for his rights. While there "he was once more confined to his bed by a tormenting attack of the gout, aggravated by the sorrows and disappointments which preyed upon his heart." From this couch of anguish he addressed one more pathetic appeal to the justice of the King, but all in vain! He sought consolation in devoutly reading the prophecies of the Holy Scriptures and the writings of the fathers of the church, and wrote a religious book and a final long letter, full of poetic mysticism, to that selfish and ungrateful King Ferdinand, the noble and magnanimous Queen Isabella having expired the year before. In making a hurried psychological study of these two opuscles, I find that for the third time the intellect of Columbus was clouded with delusion. The extravagances of his overwrought imagination must not, however, be entirely judged as they appear at the present day. They were in perfect sympathy with the quintessence of those times, when the spirit of the Crusaders was still rampant, when the conquest and fanatical expatriation of the Moslem had just been accomplished, and the Inquisition permeated, enslaved, and terrorized the whole Spanish kingdom.

So poor and helpless at last he found himself, after uselessly following the court from place to place, that he accepted the modest home offered him by kind-hearted and charitable Gil Garcia, a sailor, at Valladolid, Magdalen street (now called Colón), house No. 7. There, propped up in his lowly bed, suffering just as much from the cardiac complications of chronic rheumatism as from mental anguish and dejection and want of proper medical attendance, looking a great

deal older than he really was, but with loftiness of heart, the religious enthusiasm of an old prophet, and Christ-like forgiveness for all his persecutors, under those long, curling white hairs of his, and the gray robe of the order of St. Francis, of whom he had been a great devotee, in which he begged to be clothed and buried, he was uttering words which, to anybody unacquainted with his life, would have seemed very strange indeed. For he was speaking to his two sons and his confessor, Fray Gaspar de la Misericordia, of little else but of another world—not the world of the unknown and unknowable, nor the house not made with hands, eternal in the heavens, to which he was soon to go, but of a new world on this planet of ours, where he had been, of which he was the first to give a faithful account, and to bring from it men of an unheard-of race, and most wonderful specimens of the animal and vegetable kingdoms; a world which should be forever associated with his name, and which will be without any doubt for all coming ages an inexhaustible field for commerce, for industry, for agriculture, for benevolence, philanthropy, and liberty—a true material salvation of the whole human race.

He took his departure from this life on Ascension day, May 20, 1506, a servant satisfied with his work and honorably dismissed from the visible terraqueous globe, which he had very much enlarged, to go to the invisible and everlasting hereafter, whither all of us are marching on, pronouncing with great unction these sublime Latin words: "*In manus tuas, Domine, commendo spiritum meum.*"

What was the cause of Columbus's death, and what part did the medical profession take in the discovery of America?

I have just remarked that he died from the cardiac complications of chronic rheumatism, thus contradicting all the standard historical authorities who assert he was a victim of gout. My humble opinion is that the chronic form of polyarticular rheumatism was not developed slowly, but succeeded to an acute attack, and that this first invasion of the disease occurred on the last days of June, 1498, after Columbus left the Cape Verde Islands, on his third voyage. "The atmosphere was loaded with clouds and vapors; neither sun nor stars were to be seen; a sultry, depressing temperature prevailed," says Washington Irving. A little farther along in his narrative the same high historical authority adds that on July 13 the ships "had entered a region where the whole sea was like a mirror, and the vessels remained almost motionless, with flapping sails; the crews panting under the heat of a vertical sun, unmitigated by any refreshing breeze." The sailors lost all strength and spirits, and there was in the atmosphere, owing to drizzling showers, that combination of heat and moisture so well adapted for a genuine attack of acute rheumatism, and entirely unfavorable for the development of a paroxysm of gout. But the presence of the rheumatic poison was clearly evident in the accompanying "violent fever." Gout is not ushered in by high fever, and during the hours of severe suffering the skin usually remains dry, a general sense of relief being experienced just as soon as a profuse perspiration sets in. A warm climate exerts for that reason a beneficial effect on the occurrence of the seizures of gout. As for the peculiarity of the first attack making its appearance at night, between the hours of 12 midnight and 5 a. m., I can not say anything, because the exact time at which it occurred is nowhere recorded.

Those writers who have minutely described the last few months of the life of Christopher Columbus state that when he was confined in bed his body was extraordinarily swollen from the chest downwards. Here we have the cardiac dropsy met with as the final and fatal result of an old inflammation of the endocardium, brought about almost invariably by an attack of acute rheumatism. The shrinking and induration of the valve curtains of the heart and their tendons, as a sequel of endocarditis, and the hypertrophy and dilatation of the cardiac walls to which these pathologic changes give rise, owe their chief importance to the purely mechanical disturbance of the blood circulation thereby induced, the

action of the heart becoming more and more feeble every day until death at last closes the scene.

The cardiac complications of rheumatism (endocarditis, pericarditis, myocarditis) are by far the most frequent, being present in more than 50 per cent of all cases, and constitute the commonest cause of death in this disease. Bouillaud was the first to recognize the frequency of such accidents, and his great discovery that "their occurrence is the rule rather than the exception in rheumatic fever," has stood the test of all subsequent observers, and remains to-day one of the best established facts in clinical medicine.

Having finished saying what I had to say about the medical history of the immortal discoverer of this New World of ours, I will end by putting upon record the names of those belonging to our noble profession who directly contributed to the realization of such a momentous event in history. The clear intuitions of Avicenna, "the prince of physicians," as he was called; the advice and encouragement given to Columbus by the Florentine physician and distinguished cosmographer, Paul Toscanelli; the modest village doctor, Garcia Fernandez, who, as an improvised expert in mental diseases, won for the perambulating genius the respect and sympathy of the worthy prior of the monastery of La Rabida; the very important fact that, although it is proved beyond doubt that no priest accompanied Columbus on his first voyage, there were two representatives of our profession among his followers—Maestro Alonzo and Maestro Juan—two ship surgeons or *fisicos*; and last, but not least, the learned author of the very first scientific report on America, Dr. Diego Alvarez Chanca, who came over with Columbus on the second voyage, and saved his life during a protracted and dangerous attack of typhus fever. All these facts, scattered in many old books and pamphlets, worm-eaten in dusty archives, are here collected and presented as *pieces justificatives* of the noteworthy part taken by the medical profession in the discovery of the Western Continent.

Almost all those who have written the life and voyages of the immortal Genoese navigator—and their name is legion—speak of the probable sources of his information about the existence of a western route to the East Indies. But none of them, that I am aware of, refer to the writing of Avicenna as a possible fountain of suggestion. This eminently successful physician and most wonderfully learned man was born at the village of Afshend, in the province of Bokhara, Turkestan, Central Asia, in 980 A. D., and died in 1037. Besides his resplendent medical knowledge, he was a profound philosopher, a skillful rhetorician, an excellent geometer, well versed in astronomy and astrology, a shrewd theologian, an accomplished naturalist, and a very fine musician. During the last fourteen years of his life he wrote a considerable number of works on widely different subjects, among which his treatise entitled "De Complexionibus," section 1, chapter 1, where he cites the opinion of Aristotle expressed in his work, "De Causis Proprietatum Elementorum," is an able speculation on the existence of the antipodes.

Paolo del Pozzo Toscanelli was born at Florence in 1397, studied medicine in his native city and became one of the most famous astronomers and cosmographers of his time. On account of his great reputation in nautical science he was constantly consulted by bold navigators from different countries, who unhesitatingly followed his advice and the course marked down for them in the charts Toscanelli himself drew. He was thoroughly acquainted with the scientific and geographical literature of the Greek and Latin classics; became one of the keepers of the celebrated Florentine Library at the age of 30 years, and erected, about 1468, the famous gnomon on the uppermost part of the dome of the cathedral at Florence. He died in that city on the 15th of May, 1482. To this distinguished member of our profession Columbus applied, beseeching his opinion and advice in regard to his contemplated stupendous enterprise, as had also done a few days

before, on the same subject, the powerful King of Portugal. Like the truly scientific and generous man that he was, not only did he immediately answer the two letters of the then obscure sailor, confirming him in his views of the figure of the earth and the practicability of a voyage westward to India, but also sent him a chart drawn by his own hands, in which was marked and explained the course Columbus should follow to reach there in safety. This very chart was the one used by the admiral on his first voyage of discovery. He showed it to Martin Alonzo Pinzon, captain of the caravel *Pinta*, while sailing on the *mare incognitum*, *tenebrosum*, and both frequently sat on deck discoursing upon it. The historian Las Casas, a contemporary and friend of Columbus, says he saw it and had it in his possession. But it has been irretrievably lost.

The ancient convent of the Franciscan friars dedicated to Santa Maria de la Rábida—where Columbus halted, accompanied by his young son Diego, hungry, thirsty, dressed in tatters, full of dust, and tired from having tramped many miles—is situated at about half a league from the village of Palos de Moguer, in Andalusia, Spain. The humble physician of this little maritime town was Dr. Garcia Fernández, who enjoyed the friendship and high regard of the respected prior of the monastery, Juan Perez de Marchena. This patriotic friar detained Columbus there as his guest, and, diffident of his own judgment as to the sanity of the distinguished-looking foreigner, sent for his scientific friend, the village doctor, to converse with him and to inquire into his mental state. Dr. Fernandez was equally struck with the intelligent appearance and entertaining conversation of Columbus. He discussed with him several geographical and astronomical topics, and became convinced that he by no means was talking to a madman but to a genius. His clear discernment at once detected the possibility of the adventure Columbus was pursuing, and won for him, with his favorable report to the prior, the good will and invaluable aid of that influential religious man. What the result would have been if that unassuming and kind village doctor had given an unfavorable opinion nobody can tell.

Among the few brave men who dared accompany Columbus on his first voyage of discovery to America were two representatives of our philanthropic profession. Maestro Alonzo was the name of one, and Maestro Juan that of the other. The first seems to have been the better known of the two, and came over in the caravel *Santa Maria*, commanded by Columbus, while the second was more of a friend of Martin Alonzo Pinzon, and embarked in his vessel, *Pinta*. Maestro Juan remained at the little fort of Navidad when Columbus returned to Spain, being one of the thirty-eight men massacred by the native Indians of San Domingo, thus paying with his life for his professional devotion. The small band of foolhardy Spanish colonizers were under his medical care.

I have already referred to Dr. Diego Alvarez Chanca, who came with Columbus on his second voyage, and saved his life and that of many hidalgos at the point of death in the Island of Hispaniola or San Domingo. The account given by this distinguished man of science to the municipal council of his native city is undoubtedly an unpretentious evidence of the wide range of his scientific knowledge, and constitutes the first sketch of the flora, the fauna, the ethnology, and climatology of our dear American Continent. He also wrote, on his return to Spain, a work entitled "*Comentum Novum in Parabolis Divi Arnaldi de Villanova*," published at Seville in 1514.

In conclusion, we, as a class, have sufficient reason to feel proud of the active part taken by members of the medical profession in the discovery of this beautiful land of ours, where the "divine right of kings" is no longer possible, and where the great Chicago World's Columbian Fair has given imperishable existence to the memory of its discoverer.
